EDITORS FOR THE CHEMICAL RUBBER CO.

Editor-in-Chief

ROBERT C. WEAST, Ph.D.

Vice President, Research, Consolidated Natural Gas Service Company, Inc.
Formerly Professor of Chemistry at Case Institute of Technology
Cleveland, Ohio

Coordinating Editor

GEORGE L. TUVE, Sc.D.

Formerly Professor of Engineering at Case Institute of Technology

Editor-in-Chief of Mathematics

Samuel M. Selby, Ph.D.	*Distinguished Professor of Mathematics and Chairman Mathematics Department, University of Akron, Ohio*

Contributing Editor of Mathematics

Brian Girling, M.Sc., F.I.M.A.	*The City University, London, E.C.1, England*

Editor of Statistics

William H. Beyer, Ph.D.	*University of Akron, Akron, Ohio*

Editors of Life Sciences

Willard R. Faulkner, Ph.D.	*Vanderbilt University, Nashville, Tennessee*
Thomas E. Furia	*Geigy Chemical Corporation, Ardsley, New York*
John W. King, M.D., Ph.D.	*The Cleveland Clinic Foundation, Cleveland, Ohio*
T. D. Luckey, Ph.D.	*University of Missouri, Columbia, Missouri*
M. Miyakawa, Ph.D.	*School of Medicine, Nagoya University, Japan*
Neal S. Nelson, Ph.D.	*Radionuclide Toxicology Lab., Cincinnati, Ohio*
F. E. Shideman, M.D., Ph.D.	*University of Minnesota, Minneapolis, Minnesota*
Herbert A. Sober, Ph.D.	*National Institutes of Health, Bethesda, Maryland*
Irving Sunshine, Ph.D.	*Cuyahoga County Coroner's Office, Cleveland, Ohio*

Editors of Engineering Sciences

C. Howard Adams	*Monsanto Co., St. Louis, Missouri*
Ray E. Bolz, D.Eng.	*Case-Western Reserve University, Cleveland, Ohio*
Donald F. Gibbons, Ph.D.	*Case-Western Reserve University, Cleveland, Ohio*

Editor of Nuclear Sciences

Yen Wang, M.D., D.Sc.(Med)	*University of Pittsburgh, Pittsburgh, Pennsylvania*

Editors of Organic Chemistry

Saul Patai, Ph.D.	*Hebrew University of Jerusalem, Israel*
Zvi Rappoport, Ph.D.	*Hebrew University of Jerusalem, Israel*

Editor of Laboratory Safety

Norman V. Steere	*Division Safety Engineer, The 3 M Company, St. Paul, Minnesota* *Formerly Safety Engineer, University of Minnesota Minneapolis, Minnesota*

Preface to the Forty-Ninth Edition

Revision of a single volume reference book which has been previously revised forty-seven times since the year 1913 is a challenge. Valuable information is not going out of date as rapidly as new, useful information and data are being developed. Thus, maintaining a book within a reasonable physical size presents a problem. The book must be maintained within certain bounds even though scientists demand, and deservedly so, more extensive tables of the highest accuracy in order that the previously existing frontiers of scientific knowledge can be exceeded.

Computers and calculators are commonplace today. This gives the editor serious concern as to the advisability of continuing the rather extensive section of mathematical tables in the Handbook of Chemistry and Physics. On the other hand, presence of computors and calculators does not dictate that all of the programs and data necessary for such programs are available in all of the laboratories. For that reason the decision was made not to reduce the mathematical content of the Handbook for the forty-ninth edition.

The Handbook of Chemistry and Physics cannot list all types of data that are useful to all areas of the physical sciences; space does not permit this. However, in this present edition there is a list of all laboratories, data evaluation centers, data compilation centers, etc. which are cooperating with the Office of Critical Tables. This rather lengthy list is located at the back of the Handbook immediately preceding the index. This list presents locations where critical data are being generated, evaluated or compiled. The availability of such data is also indicated in most instances.

This forty-ninth edition contains approximately two hundred pages of new information. Information on these pages includes: X-Ray Crystallographic Data of Minerals, X-Ray Atomic Energy Levels, X-Ray Wavelengths of the Elements, Tables of the Properties of Semiconductors, Heat Capacity of Some Common Organic Compounds, Physical Properties of Pigments, Properties of Some Commercial Plastics, Sources of Critical Data, Selected Values of Dipole Moments for Molecules in the Gas Phase, Volume Properties of Ordinary Water, Density of Deuterium Oxide, Viscosity of Water from 0 to 100C, certain tables from the ASME 1967 Steam Tables, and some new Definitions and Formulas.

In keeping with past practice, certain of the tables have been revised by use of more recent data and information. Among these tables are: Critical Temperatures and Pressures, Properties of Elementary Particles, Nuclear Spins, Moments and Magnetic Resonance Frequencies, Specific Gravity of Aqueous Invert Sugar Solutions, Derived Units from Fundamental Units, Definitions and Formulas, and Far Infrared Correlation Charts.

In addition to the revisions and additions, corrections have been made of all known errors which were in the 48th and earlier editions. Sincere gratitude is expressed to all who have written regarding these errors or who have made suggestions for further improvement of the book.

Robert C. Weast

Fire Precautions and Chemical Hazards xxv

MATHEMATICAL TABLES
SECTION A

Use of Mathematical Tables A1–A7
Conversion Tables and Factors A8
Numerical Constants A9
Miscellaneous Constants A10
Decimal Equivalents of Common Fractions A11
Multiples of $\frac{\pi}{2}$ A11
Four-Place Logarithms A12–A13
Four-Place Common Logarithms of Decimal Fractions A14–A15
Four-Place Antilogarithms A16–A17
Five-Place Logarithms A18–A35
Logarithms A36–A39
Logarithms of the Trigonometric Functions A40–A62
Natural Trigonometric Functions A63
Natural Sines, Tangents, Cotangents, Cosines, Secants and Cosecants A63–A86
Natural Trigonometric Functions for Angles in Degrees and Decimals A87–A88
Logarithms of Trigonometric Functions for Angles in Degrees and Decimals A89–A90
Natural Functions for Angles in Radians A91
Logarithms of the Functions for Angles in Radians A92
Natural Functions for Angles in π Radians A93
Haversines A93–A94
Natural or Naperian Logarithms A95–A102
Exponential Functions A103–A109
Hyperbolic Functions A110–A117
Mils-Radians-Degrees A117
Degrees-Radians A118–A120
Degrees, Minutes, and Seconds to Radians A121
Radians to Degrees, Minutes, and Seconds A121
Degrees and Decimal Fractions to Radians A122
Radians to Degrees and Decimals A122
Multiples and Fractions of π Radians in Degrees A122
Conversion of Angles from Arc to Time A122
Minutes and Seconds to Decimal Parts of a Degree A123
Numerical Tables:
Reciprocals, Circumference and Area of Circles A124–A133
Squares, Cubes and Roots A134–A153
Powers of Numbers, 4th to 8th inclusive, Table A154
Powers of Two A155
Factorials and Their Logarithms A155

MATHEMATICAL TABLES
SECTION A (Continued)

Factors for Computing Probable Errors A156
Probability of Occurrence of Deviations A157
Factorials, Exact Values and Reciprocals A157
Normal Curve of Error, Areas, Ordinates and Derivatives A157–A160
Statistical Tables:
- t Test of Significance and F Test for Equality of Variance, Explanation A160
- t Test of Significance between Two Sample Means, Table A161
- Chi Square Table A162
- F Test for Equality of Variances, Table A163–A165

Elliptic Integrals:
- Complete Elliptic Integrals A166
- Elliptic Integrals of the First Kind $F(k,\phi)$ A167–A169
- Elliptic Integrals of the Second Kind $E(k,\phi)$ A170–A171

Factors and Primes A172–A181
Calculus:
- Derivatives A182–A184
- Integrals A191–A231
- Gamma Function A232

Bessel Functions $J_0(x)$ and $J_1(x)$ A232
Bessel Functions for Spherical Coordinates A232
Hyperbolic Bessel Function A233
Sine, Cosine and Exponential Integrals A233
Laplace and Fourier Transforms A234–A237
Differential Equations A238–A243
Algebra:
- Factors and Expansions A244
- Powers and Roots A244
- Proportion A244
- Sum of Powers of Integers A244
- Sums of Numbers A245
- Arithmetical Progression A245
- Geometrical Progression A245
- Factorials A245
- Permutations A245
- Combinations A245
- Quadratic Equations A245
- Cubic Equations A245
- Partial Fractions A246–A247
- Approximations A247

Series, Algebraic
- Binomial A247
- Reversion of Series A247
- Taylor's A248
- Maclaurin's A248
- Exponential A248
- Logarithmic A248
- Trigonometric A248
- Fourier A248
- Auxiliary Formulas for Fourier Series A249
- Bernoulli Numbers and Euler Numbers A249

Vector Analysis A249–A251
Special Numerical Relations A251
Stirling's Formula A251
Binomial Coefficients A252
Finite Differences A252
Statistics:
- Central Measures A253
- M-Tiles A253
- Measures of Dispersion and Skewness A253
- Class Interval A254

MATHEMATICAL TABLES
SECTION A (Continued)

Least Squares A254
Simple Correlation A254
Probability A255
Mensuration Formulae: A256–A259
Plane Figures Bounded by Straight Lines, Formulae A256
Area, Radius of Inscribed and Circumscribed Circles for Regular Polygons, Table A256
Plane Figures Bounded by Curved Lines A257
Solids Bounded by Planes A258
Surface and Volume of Regular Polyhedra A258
Solids Bounded by Curved Surfaces A258
Simpson's Rule for Irregular Areas A259
Prismoidal Formula A259
Trigonometric Formulas: A259–A263
Trigonometrical Functions in a Right-angled Triangle A259
Relations Between Degree of Accuracy of Computed Lengths and Angles A259
Signs and Limits of Value Assumed by the Functions A259
Graphs of the Trigonometric Functions A260–A261
Value of the Functions of Various Angles A261
Exponential Definitions of Circular Functions A261
Relations of the Trigonometric Functions A261
Functions of Sums of Angles A261
Functions of Multiple Angles A261–A262
Miscellaneous Relations (Trigonometric) A262
Inverse Trigonometric Functions A262
Relations between Sides and Angles of Any Plane Triangle A262
Relations of Any Spherical Triangle A263
Napier's Rules for Right Spherical Triangles A263
Analytical Geometry: A264–A266
Formulas A264
Transformation of Coordinates A265–A266
Hyperbolic Functions: A265–A267
Exponential Definitions of Hyperbolic Functions and Their Power Series A266
Relations of the Hyperbolic Functions A266–A267
Inverse Hyperbolic Functions A267
Relations to Circular Functions, Hyperbolic A267
Gudermannian Function, Relation to Hyperbolic A267
Complete Elliptic Integrals A267

Fire Precautions and Chemical Hazards

Acetone.—Dilute with a spray of water to avoid spread of burning liquid. Use suitable gas mask.

Alcohol.—See under acetone.

Ammonia.—Use water and dilute acid. Use suitable gas mask.

Benzol or Benzene.—Use water to cool containers which are endangered; extinguish flame with sand, earth, fire-foam or carbon tetrachloride fire extinguishers. Use suitable gas mask.

Calcium Carbide.—Do not use water as this generates acetylene, an inflammable and explosive gas; cut off electric current to avoid ignition of gas. Remove containers to a dry place. Use gas mask.

Carbon Disulfide.—Use water to cool containers which are endangered; extinguish blaze with sand, earth, fire-foam or carbon tetrachloride fire extinguishers. Use suitable gas mask.

Carbon Tetrachloride.—When a carbon tetrachloride type extinguisher is used on a fire in a confined space, the fire should be attacked from outside the enclosure, if possible, or the area should be vacated immediately after the fire is out. No one should return to the enclosure until the air is cleared of smoke and fumes. These precautions should be observed regardless of the means by which the fire is extinguished, however, since fire in a confined space rapidly produces a toxic atmosphere.

Do not put carbon tetrachloride on a sodium fire, violent explosions may be caused.

Celluloid.—Use large volumes of water and sand. The smoke contains oxides of nitrogen which are injurious. Use suitable gas mask.

Chlorine.—Spray with water. The pungent nature of the gas makes the use of a gas mask imperative.

Collodion.—See under carbon disulfide.

Ether.—See under carbon disulfide.

Gasoline.—See under carbon disulfide.

Hydrochloric Acid.—Use large volumes of water also chalk or soda. Use gas mask.

Hydrocyanic or Prussic Acid.—Suitable gas mask is essential because of the extremely poisonous nature of the vapors. Provide ventilation.

Lacquer Solvents.—See under carbon disulfide.

Magnesium.—Do not use water. Use sand or earth to extinguish flames. Remove containers to a dry place.

Nitric Acid and Oxides of Nitrogen.—Use large volumes of water. Do not use sand or earth. Use gas mask.

Potassium.—Do not use water. Remove containers to a dry place. Extinguish flames with sand or earth. For storage, potassium is kept immersed in petroleum.

Potassium Hydroxide.—Use large volumes of water or dilute acids.

Phosphorus.—Use water and wet sand. Use gas mask. For storage, white phosphorus must be kept immersed in water. Red phosphorus is less dangerous.

Sodium.—See under potassium.

Sodium Hydroxide.—See under potassium hydroxide.

Sulfur.—Extinguish with water or sand. Use gas mask.

Sulfuric Acid.—See under hydrochloric acid.

Turpentine.—See under acetone.

USE OF MATHEMATICAL TABLES

For a complete discussion of the principles and use of mathematical tables, textbooks on the subject should be consulted. The following brief statements are intended to give only sufficient information to make possible the intelligent use of the tables, omitting for the most part any attempt at treating the theory and principles.

Exponential Method of Expressing Numbers—For convenience in writing and manipulation, numbers are often expressed as factors of appropriate powers of 10. The following examples will illustrate:

2,380,000,000.	may be written	2.38×10^{9}
238.	may be written	2.38×10^{2}
.238	may be written	2.38×10^{-1}
.000000238	may be written	2.38×10^{-7}

Logarithms—The logarithm of a number is the exponent of that power to which another number, the base, must be raised to give the number first named. Any positive number greater than 1 might serve as a base. Two have been selected, yielding two systems of logarithms. One base, 2.718 . . . . usually indicated by the letter *e*, gives rise to a system of logarithms convenient in higher mathematics. These are called natural, Napierian, or hyperbolic logarithms. Reference will be made to their use in a subsequent paragraph.

The other base used is 10, giving logarithms particularly adapted to use in computation, called common or Briggsian logarithms. Tables of logarithms given without designation are invariably of this latter type.

Since most numbers are irrational powers of ten, a common logarithm, in general, consists of an integer which is called the characteristic and an endless decimal, the mantissa.

It is to be observed that the common logarithms of all numbers expressed by the same figures in the same order with the decimal point in different positions have different characteristics but the same mantissa. To illustrate:—if the decimal point stands after the first figure of a number, counting from the left, the characteristic is 0; if after two figures, it is 1; if after three figures, it is $\overline{2}$, and so forth. If the decimal point stands before the first significant figure the characteristic is -1, usually written $\overline{1}$; if there is one zero between the decimal point and the first significant figure it is 2 and so on. For example: log 256 = 2.40824, log 2.56 = 0.40824, log 0.256 = $\overline{1}$.40824, log 0.00256 = $\overline{3}$.40824. The two latter are often written log 0.256 = 9.40824 − 10, log 0.00256 = 7.40824 − 10.

A method of determining characteristics of logarithms is to write the number with one figure to the left of the decimal point multiplied by the appropriate power of 10. The characteristic is then the exponent used. For example:

$256{,}000{,}000 = 2.56 \times 10^{8}$	log = 8.40824
$0.000000256 = 2.56 \times 10^{-7}$	log = $\overline{7}$.40824 or 3.40824 − 10

Inasmuch as the characteristic may be determined by inspection the mantissas only are given in tables of common logarithms.

To find the logarithm of a number:

For a number of four figures, take out the tabular mantissa on a line with the first three figures of the number and under its fourth figure. The characteristic is determined as previously explained.

For a number of less than four figures, supply zeros to make a four figure number and take the value of the mantissa from the tables as before. For example: log 2 = log 2.000 = 0.30103.

For a number of more than four figures, take the tabular value of the mantissa for the first four figures; find the difference between this mantissa and the next greater tabular mantissa and multiply the difference so found by the remaining figures of the number as a decimal and add the product to the mantissa of the first four figures. For example: to find log 46.762.

$$\log 46.76 = 1.66987$$

Tabular difference between this mantissa and that for 4677 is .00010.

$$\begin{aligned} \therefore \log 46.762 &= 1.66987 + .2 \times .00010 \\ &= 1.66987 + .00002 \\ &= 1.66989 \end{aligned}$$

To find the number corresponding to a given logarithm:

If the mantissa is found exactly in the table, join the figure at the top which is directly above the given mantissa to the three figures on the line at the left and place the decimal point according to the characteristic of the logarithm. For example, $\log^{-1}$ (antilogarithm) 3.39967 = 2510.

If the mantissa is not found exactly in the table it is necessary to interpolate. For example, $\log^{-1}$ 3.40028 = 2513. + $\frac{9}{18}$ = 2513.5.

The column of proportional parts at the right of each page of the table shows, under the heading of the various tabular differences, the parts of these differences which correspond to the digits from 1 to 9 in the fifth place. This makes it possible to take out a logarithm for a five figure number or to find an antilogarithm of the same number of significant figures with increased facility, usually by inspection.

The following formulae express the relations on which the use of logarithms is based:

$$\log ab = \log a + \log b$$

$$\log \frac{a}{b} = \log a - \log b$$

$$\log a^n = n \times \log a$$

$$\log \sqrt[n]{a} = \frac{\log a}{n}.$$

The following examples will serve as illustrations:

1. $52600 \times 0.00381 \times 2.74 = 549.1$

$$\begin{aligned} \log 52600 &= 4.72099 \\ \log 0.00381 &= \bar{3}.58092 \\ \log 2.74 &= 0.43775 \\ \text{Sum:} \quad &= 2.73966 \\ \text{Antilogarithm} &= 549.1 \end{aligned}$$

The sum is the logarithm of the product, the mantissa of which is 73966. On looking up this mantissa in the logarithm tables we see that it corresponds to the digits 5491. The characteristic is 2, hence there are three figures before the decimal point. The number corresponding to the logarithm, called the antilogarithm, is 549.1.

2. $0.00123 \div 52.7 = 0.00002334$

		An Alternative method:	
$\log 0.00123$	$= \bar{3}.08991$	$\log 0.00123$	$= 7.08991 - 10$
$\log \quad 52.7$	$= 1.72181$	$\log \quad 52.7$	$= 1.72181$
Subtracting	$\bar{5}.36810$		$5.36810 - 10$
Antilog	0.00002334		

The characteristic $\bar{5}$ (5. -10) shows four zeros after the decimal point before the first significant figure.

3. $\dfrac{273 \times 780}{292 \times 760} \times 15 \times 0.09 = 1.295$

$\log 273$	$= 2.43616$	$\log 292$	$= 2.46538$
$\log 780$	$= 2.89209$	$\log 760$	$= 2.88081$
$\log \quad 15$	$= 1.17609$		
$\log 0.09$	$= \bar{2}.95424$	$\log$ denominator	$= 5.34619$
$\log$ sum	$= 5.45858$		

$\log$ numerator	$= 5.45858$
$\log$ denominator	$= 5.34619$
subtracting	$= 0.11239$
antilogarithm	$= 1.295$

As division may be accomplished by multiplying by the reciprocal of a number, the above may be considerably simplified. The logarithm of the reciprocal of a number, called the cologarithm, is readily obtained from the table by subtracting the logarithm of the number from zero. This may readily be read off from the table of mantissas. Change the sign of the characteristic algebraically adding to it -1, then mentally subtract each figure of the mantissa from 9 proceeding from left to right, the last figure being subtracted from 10. The example then is:

$\log \quad 273$	$= 2.43616$
$\log \quad 780$	$= 2.89209$
$\log \quad 15$	$= 1.17609$
$\log \quad 0.09$	$= \bar{2}.95424$
colog 292	$= \bar{3}.53462$
colog 760	$= \bar{3}.11919$
	0.11239

4. $(0.00098)^4 = 9.224 \times 10^{-13}$

		An alternative method:	
$\log 0.00098$	$= \bar{4}.99123$	$\log 0.00098$	$= 6.99123 - 10$
	4		4
	3.96492(a)		$27.96492 - 40$
$\bar{4} \times 4$	$\bar{16}.$ (b)		or $7.96492 - 20$
			or $\bar{13}.96492$
$\log (0.00098)^4$	$= \bar{13}.96492$(c)		
antilog	$= 9.224 \times 10^{-13}$	antilog	$= 9.224 \times 10^{-13}$

In the above it will be noted that the mantissa is always positive hence the multiplication of the mantissa shown at (a) while (b) shows the multiplication of the characteristic. (c) is the algebraic sum.

5. $\sqrt[5]{492} = 3.455$
   $\log 492 = 2.69197$

Dividing the logarithm by 5 gives as the logarithm of the root 0.53839 the antilogarithm of which is 3.455 both characteristic and mantissa being positive. When the characteristic is negative and not evenly divisible by the root to be taken a modification of the logarithm is necessary.

6. $\sqrt[3]{0.000372} =$
   $\log 3.72 \times 10^{-4} = \bar{4}.57054$ (a)
   $= 26.57054 - 30$ (b)

dividing (b) by 3 gives $8.85685 - 10$ which may be written $\bar{2}.85685$ and is the logarithm of the root sought, the antilogarithm of which is 0.07192.

7. $0.000372^{1.2} = 0.000076674$
   $\log 0.000372 = \bar{4}.57054$
   or $6.57054 - 10$
   1.2
   $7.88465 - 12$
   antilogarithm 0.000076674

8. $(0.000372)^{-1.32} = 33642$
   colog 0.000372 $= 3.42946$
   1.32
   4.52689
   antilogarithm 33642

Four-Place Logarithms—This short table on two facing pages makes possible logarithmic computation precise to four significant figures, (three without interpolation). The mantissa is given complete and the proportional parts indicated for each line.

Four-Place Antilogarithms—Some computers prefer to use separate tables for determining antilogarithms; the table being entered from the margins with the logarithm and the number being found in the body of the table. Such a table is given to accompany the four-place logarithms.

Five-Place Logarithms For computation involving five significant figures, (four without interpolation) the five-place table will be adequate. Since the first two figures will be the same for several lines of the table they are given in the first line only. The point at which these first two figures change is indicated by an asterisk. While space does not permit the proportional parts for each line, tables will be found for each tabular difference.

The supplementary table following the five-place logarithms, giving seven-place logarithms for numbers of five significant figures from 10,000 to 12,000 will be found convenient to increase precision and avoid the inconvenience of interpolation where the differences are large.

Logarithms of the Trigonometric Functions Logarithms of the functions are given for each minute from 0–360°.

The quantity -10 is to be appended to all logarithms of the sine and cosine, to logarithms of the tangent from 0–45° and of the cotangent from 45–90°.

With degrees indicated at either side of the top of the page use the column headings at the top. With degrees stated at the bottom of the page use the column designations at the bottom.

With degrees at the left (top or bottom) use the minute column at the left, and with degrees on the right side of the page use the minute column at the right.

To illustrate the proper employment of headings for angles in the four quadrants—

$\log \sin\ 6° 24' = 9.04715 - 10$	$\log \sin\ 186° 24' = 9.04715 - 10$
$\log \sin\ 83° 15' = 9.99698 - 10$	$\log \sin\ 263° 15' = 9.99698 - 10$
$\log \cos\ 96° 41' = 9.06589 - 10$	$\log \cos\ 276° 41' = 9.06589 - 10$
$\log \cos\ 173° 49' = 9.99747 - 10$	$\log \cos\ 353° 49' = 9.99747 - 10$

For the accurate determination of values where the tabular differences are large, the values of CS and CT are given. The following equations indicate their use.

To find the logarithm of the functions of an angle:

For angles 0–3°	For angles 87–90°
$\log \sin \theta = \log \theta'' - \mathrm{CS}$	$\log \cos \theta = \log (90° - \theta)'' - \mathrm{CS}$
$\log \tan \theta = \log \theta'' - \mathrm{CT}$	$\log \cot \theta = \log (90° - \theta)'' - \mathrm{CT}$
$\log \cot \theta = \operatorname{colog} \tan \theta$	$\log \tan \theta = \operatorname{colog} \cot \theta$

To find the angle:

For angles 0–3°	For angles 87–90°
$\log \theta'' = \log \sin \theta + \mathrm{CS}$	$\log (90° - \theta)'' = \log \cos \theta + \mathrm{CS}$
$\log \theta'' = \log \tan \theta + \mathrm{CT}$	$\log (90° - \theta)'' = \log \cot \theta + \mathrm{CT}$

In the above expressions, θ'' and $(90° - \theta)''$ are used to indicate the value of the angles expressed in seconds. The values in the body of the table are the cologarithms and should be used as indicated above.

The values of the logarithms S and T are also given in a separate table. For these the following relations hold:

To find the functions of an angle.

$\log \sin \theta = \log \theta'' + \mathrm{S}$	$\log \cos \theta = \log (90° - \theta)'' + \mathrm{S}$
$\log \tan \theta = \log \theta'' + \mathrm{T}$	$\log \cot \theta = \log (90° - \theta)'' + \mathrm{T}$

To find the angle.

$\log \theta'' = \log \sin \theta - \mathrm{S}$	$\log (90° - \theta)'' = \log \cos \theta - \mathrm{S}$
$\log \theta'' = \log \tan \theta - \mathrm{T}$	$\log (90° - \theta)'' = \log \cot \theta - \mathrm{T}$

Where the values of CS and CT are given, the angles expressed in seconds are given in the supplementary column at the left.

The tabular differences are given under the headings "d" and "c.d.," the latter referring to the common difference for the tangent and cotangent. Tables of proportional parts ("P.P.") facilitate interpolation. At the bottom of each column will be found special proportional parts between the tabular differences for the tangent or cotangent and those for the sine or cosine. These are useful when one function is to be obtained directly from the other without determining the angle.

For example, suppose log tan θ is given as 9.67644 and log cos θ is required. The difference between the given logarithm and that given in the table, 9.67622 (opposite 25° 23′), is 22. The tabular differences of the two logarithmic functions at this place are 32 and 6. In the proportional table for $\frac{6}{32}$, 22 corresponds to 4; this, subtracted from the tabular logarithmic cosine 9.95591, gives the required log cos θ = 9.95587.

The symbols $\bar{5}$ and $\dot{5}$ are used to indicate how the terminal 5 has been derived. For example, the logarithm 8.83075 is more fully given as 8.8307495 while the value 9.4082$\dot{5}$ is derived from 9.4082539. Thus, in rounding off to four places, a number ending in $\bar{5}$ should be decreased but a number ending in $\dot{5}$ should be increased.

Natural Trigonometric Functions—Values of the natural trigonometric functions of angles are given for each minute from 0–360°.

For degrees indicated at the top of the page use the column headings at the top. For degrees indicated at the bottom use the column indications at the bottom.

With degrees at the left of each block (top or bottom), use the minute column at the left and with degrees at the right of each block use the minute column at the right.

Natural Functions and their Logarithms are given for angles in degrees and tenths from 0 to 90 degrees.

Natural Functions and their Logarithms are given for angles in radians and hundredths, from 0 to 2 radians.

Haversines—Values of $(1 - \cos \theta)/2$ for angles between 0 and 180° are given to four significant figures. The four-place mantissas of the logarithms of the haversines are also given. The correct characteristic must be provided in each case.

The listed values of the haversines were derived from values which were computed to seven significant figures. The logarithms were independently derived from the more exact values of the haversines and are, therefore, in many cases not the exact value of the logarithm of the haversine as listed. This is notably true at the beginning of the table where the logarithm can be given with more exactness than the function.

Natural Logarithms—The natural logarithms of numbers from 0.000 to 999. are given in a group of four tables. The method of finding logarithms of numbers not included in the tables is indicated at the beginning of the third page. A convenient table of constants occurs at the top of the fourth page.

The first page gives the natural logarithms of numbers from 0.000 to 0.499. Since the characteristics change rapidly for the smaller numbers, they are indicated *above* the mantissa in the first line. In the second and following lines the characteristics are given at the left only. For example, $\log_e 0.004 = -5.52146$; $\log_e 0.014 = -4.26870$.

The succeeding pages give the natural logarithms of numbers up to 999.

Exponential Functions—Values of e^x, $\log e^x$ and e^{-x} where e is the base of the natural system of logarithms 2.71828 . . . and x has values from 0 to 10. Facilitating the solution of exponential equations, these tables also serve as a table of natural or Napierian antilogarithms. For instance if the logarithm or exponent $x = 3.26$ the corresponding number or value of e^x is 26.050. Its reciprocal e^{-x} is .038388.

Hyperbolic Functions—The table gives the values and logarithms of the hyperbolic sine x, cosine x, tangent x and cotangent x for values of x from 0 to 10.

Degrees-Radians—This table gives the value in radians to five significant figures; for each 10 minutes from 0° 0′ to 90° 0′; for each degree from 90 to 180; for each 10 degrees from 180 to 480. Values are also given for each minute from 0–60′ and for each second from 0–60″.

Tables are also provided to facilitate changing from degrees and decimal fractions to radians, from decimal fractions of a degree to minutes and seconds and the reverse operations.

Numerical Tables—The first section gives the reciprocals of numbers from 0 to 1000 and circumferences and areas of circles with diameters having these values. Reciprocals and circumferences for values not listed can be obtained by an appropriate shift of the decimal point.

The second section is devoted to squares, cubes and roots. The squares and cubes from 1 to 1000 are given exactly. The roots are given to seven significant figures. Since the square roots of $10n$ are given, values of the square roots from 1 to 10,000 may be found directly. For the square roots of numbers below and above this range, use may be made of the following relations: $\sqrt{100n} = 10\sqrt{n}$; $\sqrt{1000n} = 10\sqrt{10n}$; $\sqrt{\frac{1}{10}n} = \frac{1}{10}\sqrt{10n}$; $\sqrt{\frac{1}{100}n} = \frac{1}{10}\sqrt{n}$; $\sqrt{\frac{1}{1000}n} = \frac{1}{100}\sqrt{10n}$. For example, the square root of 0.268 may be found by using the form, $\sqrt{0.268} = \frac{1}{100}\sqrt{10 \times 268}$. The tabular value for the square root of $10n$ for 268 is 51.76872. Hence, the desired root is 0.5176872.

Values of cube roots for all numbers from 1 to 100,000 will be found directly in the table. Cube roots for numbers above or below this range will be found from the following relations: $\sqrt[3]{1000n} = 10\sqrt[3]{n}$; $\sqrt[3]{10{,}000n} = 10\sqrt[3]{10n}$; $\sqrt[3]{100{,}000n} = 10\sqrt[3]{100n}$; $\sqrt[3]{\frac{1}{10}n} = \frac{1}{10}\sqrt[3]{100n}$; $\sqrt[3]{\frac{1}{100}n} = \frac{1}{10}\sqrt[3]{10n}$; $\sqrt[3]{\frac{1}{1000}n} = \frac{1}{10}\sqrt[3]{n}$. For example, the cube root of 731,000 may be found by using the form, $\sqrt[3]{731{,}000} = 10\sqrt[3]{731}$. The tabular value of the root for 731 is 9.008223. The desired root is, therefore, 90.08223.

Powers of Numbers—This table is given to supplement the values of squares and cubes of numbers found in the preceding numerical table. The larger numbers are expressed exponentially to at least seven significant figures. The approximate value written as a whole number may be obtained by shifting the decimal point to the right by the number of places indicated in the exponent of 10 shown at the head of each group of values. For example: the approximate value of 33^8 is found in the table as 14.064086×10^{11}. Written as a whole number it is 1,406,408,600,000.

Factorials and their Logarithms—The product $n \times (n-1) \times (n-2) \times \cdots \times 1$ is called factorial n, expressed as $n!$ or $\underline{|n}$. For example: factorial $5 = 5 \times 4 \times 3 \times 2 \times 1 = 120$. Factorials are very often met with in series. For purposes of computation in such cases the table giving the values of the factorials and of their logarithms for numbers from 1 to 100 is provided. The values of the factorials are expressed exponentially to 5 significant figures.

A brief table of exact values and reciprocals of factorials is to be found on page A–91.

Factors for Computing Probable Errors—The probable error of a series of n measures $a_1, a_2, a_3 \ldots a_n$, the mean of which is m, is given by the expression,

$$e = \frac{0.6745}{\sqrt{n-1}} \sqrt{(m-a_1)^2 + (m-a_2)^2 + \cdots (m-a_n)^2}$$

The probable error of the mean is,

$$E = \frac{0.6745}{\sqrt{n(n-1)}} \sqrt{(m-a_1)^2 + (m-a_2)^2 + \cdots (m-a_n)^2}$$

The following approximate equations are convenient forms for computation,

$$e = 0.8453 \frac{\Sigma d}{\sqrt{n(n-1)}}$$

$$E = 0.8453 \frac{\Sigma d}{n\sqrt{n-1}}$$

The symbol Σd represents the arithmetical sum of the deviations.

For convenience in computing the probable error the value of several of the factors involved is given for values of n from 2 to 100.

Probability of Occurrence of Deviations—The significance of deviations is indicated by this table. The probability of occurrence of deviations as great as or greater than any specific value is given for various ratios of deviation to probable error and also with respect to the standard deviation σ. The probability of occurrence is stated in per cent or chances in 100. The odds against occurrence are also stated. The probable error is $0.6745 \times (\sigma)$.

Normal Curve of Error—If, for a large number of observations, the frequency y, of the occurrence of an error of magnitude t be plotted, a curve results whose equation may be written,

$$y = \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$$

The area, ordinates and derivatives for this curve given in the table are useful in the treatment of observational data. A text on statistical methods should be consulted for a complete explanation.

Factors and Primes—The table presents the prime factors of *all* factorable numbers and the logarithms of all prime numbers from 1 to 2000.

U. S. AND METRIC UNITS

Each unit in bold face type is followed by its equivalent in other units of the same quantity.

Acre—0.0015625 square mile (statute); 4.3560 × 10^4 square feet; 0.40468564 hectare.

Bushel—(**U. S.**)—1.244456 cubic feet; 2150.42 cubic inches; 0.035239 cubic meter; 35.23808 liters.

Centimeter—0.0328084 foot; 0.393701 inch.

Circular Mil—7.853982 × 10^{-7} square inches; 5.067075 × 10^{-6} square centimeters.

Cubic Centimeter—0.061024 cubic inch; 0.270512 dram (U. S. fluid); 16.230664 minims (U. S.); 0.999972 milliliter.

Cubic Foot—0.803564 bushel (U. S.); 7.480520 gallons (U. S. liquid); 0.028317 cubic meter; 28.31605 liters.

Cubic Inch—16.387064 cubic centimeters.

Cubic Meter—35.314667 cubic feet; 264.17205 gallons (U. S. liquid).

Foot—0.3048 meter.

Gallon (U. S. liquid)—0.1336816 cubic foot; 0.832675 gallon (British); 231 cubic inches; 0.0037854 cubic meter; 3.785306 liters.

Grain—0.06479891 gram.

Gram—0.00220462 pound (avoirdupois); 0.035274 ounce (avoirdupois); 15.432358 grains.

Hectare—2.471054 acres; 1.07639 × 10^5 square feet.

Inch—2.54 centimeters.

Kilogram—2.204623 pounds (avoirdupois).

Kilometer—0.621371 mile (statute).

Liter—0.264179 gallon (U. S. liquid); 0.0353157 cubic foot; 1.056718 quarts (U. S. liquid).

Meter—1.093613 yards; 3.280840 feet; 39.37008 inches.

Mile (statute)—1.609344 kilometers.

Ounce (U. S. fluid)—1.804688 cubic inches; 29.573730 cubic centimeters.

Ounce (avoirdupois)—28.349523 grams.

Ounce (apothecary or troy)—31.103486 grams.

Pint (U. S. liquid)—0.473163 liter; 473.17647 cubic centimeters.

Pound (avoirdupois)—0.453592 kilogram; 453.59237 grams.

Pound (apothecary or troy)—0.3732417 kilogram, 373.24172 grams.

Quart (U. S. dry)—1.10119 liters.

Quart (liquid)—0.946326 liter.

Radian—57.295779 degrees.

Rod—5.0292 meters.

Square Centimeter—0.155000 square inch.

Square Foot—0.09290304 square meter.

Square Inch—645.16 square millimeters.

Square Meter—10.763910 square feet.

Square Yard—0.836127 square meter.

Ton (short)—907.18474 kilograms.

Yard—0.9144 meter.

Change of Base

$$\log_a x = \log_b x / \log_b a$$

$$\log_{10} x = \log_e x / \log_e 10 \qquad \log_e x = \log_{10} x / \log_{10} e$$

$$\log_e x = 1/M \log_{10} x = 2.30258\ 50930 \log_{10} x$$

$$\log_{10} x = M \log_e x = 0.43429\ 44819 \log_e x$$

MISCELLANEOUS CONSTANTS

Equatorial radius of the earth = 6378.388 km = 3963.34 miles (statute).
Polar radius of the earth, 6356.912 km = 3949.99 miles (statute).
1 degree of latitude at 40° = 69 miles.
1 international nautical mile = 1.15078 miles (statute) = 1852 m = 6076.115 ft.
Mean density of the earth = 5.522 g/cm^3 = 344.7 lb/ft^3.
Constant of gravitation, 6.673 $\pm$ 0.003 $\times$ 10^{-8} cm^3/g $\times$ sec^2.
Acceleration due to gravity at sea level, latitude 45° = 980.621 cm/sec^2 = 32.1725 ft/sec^2.
Length of seconds pendulum at sea level, latitude 45° = 99.3574 cm = 39.1171 in.
1 knot (international) = 101.269 ft/min = 1.6878 ft/sec = 1.1508 miles (statute)/hr.
1 micron = 10^{-4} cm.
1 ångstrom 10^{-8} cm.
Mass of hydrogen atom = (1.67339 $\pm$ 0.00031) $\times$ 10^{-24} g.
Avogadro's number = (6.02257 $\pm$ 0.00009) $\times$ 10^{-23}/g mole.
Planck's constant = (6.62554 $\pm$ 0.00015) $\times$ 10^{-27} erg-sec.
Density of mercury at 0° C = 13.5955 g ml.
Density of water at 3.98° C = 1.000000 g/ml.
Density, maximum, of water, at 3.98° C = 0.999973 g/cm^3.
Density of dry air at 0° C, 760 mm = 1.2929 g/liter.
Velocity of sound in dry air at 0° C = 331.36 m/sec = 1087.1 ft/sec.
Velocity of light in vacuum = 2.997925 $\pm$ 0.000002) $\times$ 10^{10} cm/sec.
Heat of fusion of water 0° C = 79.71 cal/g.
Heat of vaporization of water 100° C = 539.55 cal/g.
Electrochemical equivalent of silver 0.001118 g/sec international amp.
Absolute wave length of red cadmium light in air at 15° C, 760 mm pressure = 6438.4696 A
Wave length of orange-red line of krypton 86 = 6057.802 A.
Gas Constant = 8.31432 $\pm$ 0.00034 $\times$ 10^7 erg (g mole)$^{-1}$ deg^{-1}.

* This table gives the logarithms of the decimal fractions which are negative numbers.

For example log 0.61 = −0.2147 = 9.7853 − 10. It should be noted that the entries as given can be used conveniently to find cologarithms of positive numbers. Every positive number $N = P \cdot (10)^k$, where $0 < P \leqq 1$. Since colog N = − log N, it follows that colog N = − log P − k.

For example colog 0.61 = − log 0.61 = 0.2147; colog 61 = 0.2147 − 2; and colog 0.00061 = 3.2147.

LOGARITHMS OF THE FUNCTIONS (Continued)

Natural Trigonometric Functions

Values of the trigonometric functions of angles for each minute from 0–360°.

For degrees indicated at the top of the page use the column headings at the top. For degrees indicated at the bottom use the column indications at the bottom.

With degrees at the left of each block (top or bottom), use the minute column at the left and with degrees at the right of each block use the minute column at the right.

If natural trigonometric function tables are used for angle measures greater than 90° and less than 360°, appropriate signs for the functions must be supplied in accordance with the quadrant in which the angle measure belongs.

* Values of the cosine, tangent and cotangent for angles in the table, 1.58 radians and above, are negative. As a consequence the logarithms of the functions involved are for their absolute values. For example log |cos 1.90 = 9.50959 − 10.

These functions are useful in the solution of wave equations such as the displacement equation of a sound wave in the form:

$$y = A \sin 2\pi n x$$

without the necessity of reducing the angular rotation either to radians or to degrees in order to find the value of the function.

The algebraic sign of the function follows the familiar Quadrant Law for the particular function desired. Thus a numerical value of 9.13π radians becomes (by the subtraction of the greatest multiple of 2π radians) 1.13π radians. This is the same as $.13\pi$ radians in the 3rd Quadrant, which would give, from the tables above, a value of the sine function of $-.39715$.

Submitted by J. A. Blythe Jr.

HAVERSINES

hav $\theta = \frac{1}{2}$ vers $\theta = \frac{1}{2}(1 - \cos\theta) = \sin^2 \frac{1}{2}\theta$
hav $(-\theta)$ = hav θ
hav $(180° - \theta)$ = hav $(180° + \theta) = 1 -$ hav θ
Characteristics of the logarithms are omitted.

NATURAL OR NAPERIAN LOGARITHMS (Continued)

To find the natural logarithm of a number which is $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, etc. of a number whose logarithm is given, subtract from the given logarithm $\log_e 10$, $2 \log_e 10$, $3 \log_e 10$, etc.

To find the natural logarithm of a number which is 10, 100, 1000, etc. times a number whose logarithm is given, add to the given logarithm $\log_e 10$, $2 \log_e 10$, $3 \log_e 10$, etc.

$\log_e 10 =$ 2.30258 50930	$6 \log_e 10 =$ 13.81551 05580
$2 \log_e 10 =$ 4.60517 01860	$7 \log_e 10 =$ 16.11809 56510
$3 \log_e 10 =$ 6.90775 52790	$8 \log_e 10 =$ 18.42068 07440
$4 \log_e 10 =$ 9.21034 03720	$9 \log_e 10 =$ 20.72326 58369
$5 \log_e 10 =$ 11.51292 54650	$10 \log_e 10 =$ 23.02585 09299

See preceding table for logarithms for numbers between 0.000 and 0.999.

1 second = 0.00000 48481 36811 radians	4.68557 48668–10

DEGREES—RADIANS

The table gives in radians the angle which is expressed in degrees and minutes at the side and top. Angles expressed to the nearest minute and second can readily be converted to radians by adding to the equivalent of the whole number of degrees the equivalents of the minutes and seconds found on the third page of this table.

* If 3.214 is desired in degrees, minutes and seconds it is obtained as follows:

$$
\begin{aligned}
3 &= 171^\circ\ 53'\ 14.4'' \\
.2 &= \ 11^\circ\ 27'\ 33.0'' \\
.01 &= \ \ 0^\circ\ 34'\ 22.6'' \\
.004 &= \ \ 0^\circ\ 13'\ 45.1'' \\
\hline
3.214 &= 184^\circ\ \ 8'\ 55.1''
\end{aligned}
$$

DEGREES AND DECIMAL FRACTIONS TO RADIANS

The table below facilitates conversion of an angle expressed in degrees and decimal fractions into radians. To convert 25.78 into radians, find the equivalents, successively, of 20°, 5°, 0°.7, 0°.08 and add.

Deg.	Radians	Deg.	Radians	Deg.	Radians	Deg.	Radians	Deg.	Radians

RECIPROCALS, CIRCUMFERENCE AND AREA OF CIRCLES

As a matter of convenience, the values of $1000 \times (1/n)$ are given in the table. To obtain the actual value of the reciprocal, shift the decimal point three places to the left.

Circumferences and areas of circles are given for the values of n as the diameter.

n	$1000\frac{1}{n}$	Circumference πn	Area $\frac{\pi n^2}{4}$	n	$1000\frac{1}{n}$	Circumference πn	Area $\frac{\pi n^2}{4}$

SQUARES, CUBES AND ROOTS

Roots of numbers other than those given directly may be found by the following relations:

$\sqrt{100n} = 10\sqrt{n}$; $\sqrt{1000n} = 10\sqrt{10n}$; $\sqrt{\frac{1}{10}n} = \frac{1}{10}\sqrt{10n}$; $\sqrt{\frac{1}{100}n} = \frac{1}{10}\sqrt{n}$, $\sqrt{\frac{1}{1000}n} = \frac{1}{100}\sqrt{10n}$; $\sqrt[3]{1000n} = 10\sqrt[3]{n}$; $\sqrt[3]{10{,}000n} = 10\sqrt[3]{10n}$; $\sqrt[3]{100{,}000n} = 10\sqrt[3]{100n}$; $\sqrt[3]{\frac{1}{10}n} = \frac{1}{10}\sqrt[3]{100n}$; $\sqrt[3]{\frac{1}{100}n} = \frac{1}{10}\sqrt[3]{10n}$; $\sqrt[3]{\frac{1}{1000}n} = \frac{1}{10}\sqrt[3]{n}$.

Valid for thirty or more samples.

Probability of occurrence, expressed as per cent, and odds against a deviation as great or greater than that designated is given for various ratios of the deviation to the probable error and to the standard deviation.

(From Pearl, Medical Biometry and Statistics, W. B. Saunders Company, publishers, by permission.)

Ratio dev. to P.E.	Probable occurrence %	Odds against, to 1	Ratio dev. to std. dev.	Probable occurrence %	Odds against, to 1

NORMAL CURVE OF ERROR

If x is measured in "σ-units" from the mean* the following tables give the values for the area integral

$$\int_0^t \phi(x)dx,\ \phi(x),\ \phi''(x) = (x^2-1)\phi(x),\ \phi'''(x) = (3x-x^3)\phi(x),\ \text{and}\ \phi^{iv}(x) = (x^4-6x^2+3)\phi(x)$$

for value $x = t$.

It should be noted that other probability integrals can be calculated from these tables. For example:

$$\int_0^t \phi(x)dx = \frac{1}{2}\,\text{erf}\left(\frac{t}{\sqrt{2}}\right),\ \text{where erf}\left(\frac{t}{\sqrt{2}}\right),$$

represents the error function associated with the normal curve.

To evaluate erf (2.3) proceed as follows:

$$\text{Since}\ \frac{t}{\sqrt{2}} = 2.3,\ \text{one finds}\ t = (2.3)\sqrt{2} = (2.3)(1.414) = 3.25.$$

In entry for area opposite $t = 3.25$, the value 0.4994 is given. Thus erf (2.3) = 2 (0.4994) = 0.9988.

* See index for Probability, formulae.

"t" Test of Significance Between Two Sample Means ($\bar{x}_1$ and $\bar{x}_2$).

(Use Fisher's t distribution)

Paired variates:

$$t = \frac{\bar{d}}{\sqrt{\frac{\Sigma(d_i - \bar{d})^2}{N(N-1)}}} \text{ with } N - 1 \text{ degrees of freedom}$$

where $\bar{d} = \bar{x}_1 - \bar{x}_2$
$d_1 = x_{11} - x_{21}$
$d_2 = x_{12} - x_{22}$ etc.
N = sample size

Unpaired variates:

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{\Sigma_i(x_{1i} - \bar{x}_1)^2 + \Sigma_i(x_{2i} - \bar{x}_2)^2}{N_1 + N_2 - 2}\left(\frac{1}{N_1} + \frac{1}{N_2}\right)}}$$

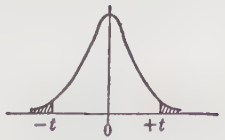
with $N_1 + N_2 - 2$ degrees of freedom

where N_1 = size of sample 1
N_2 = size of sample 2

Chi Square Table

The column headings "P" are probabilities, while the body of the table gives values of χ^2; the left column the degrees of freedom. The probability of a value $\chi^2 \geqq$ than the value specified is thus obtained. For $n = 20$, $P(\chi^2 \geqq 10.851)$ the table gives .95, and accordingly by subtraction $P(\chi^2 \leqq 10.851)$ is .05.

F Test for Equality of Variances



$$F = \frac{{\sigma_1}^2}{{\sigma_2}^2}$$

where ${\sigma_1}^2$ = variance of sample with size N_1
${\sigma_2}^2$ = variance of sample with size N_2
with $N_1 - 1$ = degrees of freedom for numerator
$N_2 - 1$ = degrees of freedom for denominator

(Use Snedecor's F distribution)

NORMAL CURVE OF ERROR
Normal Curve $\phi(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}$ (Continued)
TESTS OF SIGNIFICANCE

For degrees of freedom greater than 30, the expression $\sqrt{2\chi^2} - \sqrt{2n' - 1}$ may be used as a normal deviate with unit variance, where n' is the number of degrees of freedom.

An elliptic integral has the form $\int R(x, \sqrt{f(x)})\, dx$, where R represents a rational function and $f(x) = a + bx + cx^2 + dx^3 + ex^4$, an algebraic function of the third or fourth degree.

1. Elliptic integrals of the *first kind* are represented by

$$F(k, \phi) = \int_0^{\phi} \frac{d\Phi}{\sqrt{1 - k^2 \sin^2 \Phi}} = \int_0^{x} \frac{d\xi}{\sqrt{(1 - \xi^2)(1 - k^2\xi^2)}}, \quad x = \sin \phi,\ k^2 < 1.$$

2. Elliptic integrals of the second kind are represented by

$$E(k, \phi) = \int_0^{\phi} \sqrt{1 - k^2 \sin^2 \Phi}\, d\Phi = \int_0^{x} \frac{\sqrt{1 - k^2\xi^2}}{\sqrt{1 - \xi^2}}\, d\xi, \quad x = \sin \phi,\ k^2 < 1.$$

3. Elliptic integrals of the third kind are represented as

$$\pi(k, n, \phi) = \int_0^{\phi} \frac{d\Phi}{(1 + n \sin^2 \Phi)\sqrt{1 - k^2 \sin^2 \Phi}}, \qquad k^2 < 1,\ n \text{ an integer.}$$

Elliptic integrals of the third kind are also represented as

$$\pi_1(k, n, x) = \int_0^{x} \frac{d\xi}{(1 + n\xi^2)\sqrt{(1 - \xi^2)(1 - k^2\xi^2)}}, \qquad x = \sin \phi,\ k^2 < 1,\ n \text{ an integer.}$$

4. The complete integrals are

$$K = F\left(k, \frac{\pi}{2}\right) = \frac{\pi}{2}\left[1 + \left(\frac{1}{2}\right)^2 k^2 + \left(\frac{3}{2 \cdot 4}\right)^2 k^4 + \left(\frac{3 \cdot 5}{2 \cdot 4 \cdot 6}\right)^2 k^6 + \cdots\right]$$

$$E = E\left(k, \frac{\pi}{2}\right) = \frac{\pi}{2}\left[1 - \left(\frac{1}{2^2}\right) k^2 - \left(\frac{3^2}{2^2 \cdot 4^2}\right)\frac{k^4}{3} - \left(\frac{3^2 \cdot 5^2}{2^2 \cdot 4^2 \cdot 6^2}\right)\frac{k^6}{5} - \left(\frac{3^2 \cdot 5^2 \cdot 7^2}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2}\right)\frac{k^8}{7} - \cdots\right].$$

$$K' = F\left(\sqrt{1 - k^2}, \frac{\pi}{2}\right),\ E' = E\left(\sqrt{1 - k^2}, \frac{\pi}{2}\right)$$

5. The following relation holds between K, K', E, E', namely

$$KE' + EK' - KK' = \frac{\pi}{2}$$

6. To evaluate elliptic integrals for values outside the range contained in the following tables, the following relations are useful

$$F(k, \pi) = 2K;\ E(k, \pi) = 2E$$

$$F(k, \phi + m\pi) = mF(k, \pi) + F(k, \phi) = 2mK + F(k, \phi), \qquad m = 0, 1, 2, 3, \ldots$$

$$E(k, \phi + m\pi) = mE(k, \pi) + E(k, \phi) = 2mE + E(k, \phi), \qquad m = 0, 1, 2, 3, \ldots$$

7. If $u = F(k, \phi) = \int_0^{\phi} \frac{d\Phi}{\sqrt{1 - k^2 \sin^2 \Phi}}$ $(k^2 < 1)$,
= elliptic integral of the first kind.

$$u = \int_0^{x} \frac{dx}{\sqrt{(1 - \xi^2)(1 - k^2\xi^2)}}, \qquad \text{where } x = \sin \phi.$$

ϕ is called the amplitude of u or am u.
k is called the modulus.

$k' = \sqrt{1 - k^2}$ = the complementary modulus.

$\sin \phi = \operatorname{sn} u = x \qquad \tan \phi = \operatorname{tn} u = \frac{x}{\sqrt{1 - x^2}}.$

$\cos \phi = \operatorname{cn} u = \sqrt{1 - x^2}.$ $\qquad \Delta\phi = \operatorname{dn} u = \sqrt{1 - k^2x^2}.$

$\operatorname{am} 0 = 0.$ $\qquad \operatorname{sn} 0 = 0.$
$\operatorname{cn} 0 = 1.$ $\qquad \operatorname{dn} 0 = 1.$
$\operatorname{am}(-u) = -\operatorname{am} u.$ $\qquad \operatorname{sn}(-u) = -\operatorname{sn} u.$
$\operatorname{cn}(-u) = \operatorname{cn} u.$ $\qquad \operatorname{dn}(-u) = \operatorname{dn} u.$

$\operatorname{tn}(-u) = -\operatorname{tn} u.$
$\operatorname{sn}^2 u + \operatorname{cn}^2 u = 1.$
$\operatorname{dn}^2 u + k^2 \operatorname{sn}^2 u = 1.$
$\operatorname{dn}^2 u - k^2 \operatorname{cn}^2 u = 1 - k^2 = k'^2.$

ELLIPTIC INTEGRALS OF THE FIRST AND SECOND KIND

$$F(k, \phi) = \int_0^{\phi} \frac{d\Phi}{\sqrt{1 - k^2 \sin^2 \Phi}} \qquad \theta = \sin^{-1} k$$

ELLIPTIC INTEGRALS OF THE SECOND KIND: $E(k, \phi)$
(Continued)

FACTORS AND PRIMES

If n is prime the mantissa of its logarithm is given. If n is not prime its prime factors are given.

n	0	1	2	3	4
0	.....		**3010300**	**4771213**	2^2

EXTENDED TABLES OF FACTORS AND PRIMES

The following procedure makes possible the determination of a number between 2009 and 19,949 as being either prime, or if not, what its factors will be. It is herewith included with the kind permission of its author, Professor Leonard Caners.

The following symbols will be used:

N is the number whose factors, if any, are to be determined.
A is N with the last digit dropped. Thus if $N = 17{,}873$, $A = 1787$.
R is the range and is the integral part of the square root of N with its last two digits dropped. Thus R of $17{,}873 = 13$.
K is the key number and is found in the table below.
P_1 is a possible factor corresponding to K.
The twin series are given in the table for the sake of completeness but are not written down in actual practice.
There are two steps as outlined below.

Step I

N	K	P_1	Series	Procedure
Any number ending in 1, 3, 7, or 9, within limits stated above	$A - R$	$10R +$ last digit	$K + n$; $P_1 - 10n$ $n = 0, 1, \ldots, 2R + 1$	Beginning with K read table of Factors and Primes from left to right and look for corresponding possible factors

Step II

N ending in	K	P_1	Series	Procedure
1	$(A - 2) - 3R$	$10R + 7$	$K + 3n$; $P_1 - 10n$ $n = 0, 1, \ldots, 2R + 1$	Same as in Step I except that only every *third* entry in table of Factors and Primes is examined for corresponding possible factors
3	$A - 3R$	$10R + 1$	$n = 0, 1, \ldots, 2R + 1$	
7	$(A - 2) - 3R$	$10R + 9$	$n = 0, 1, \ldots, 2R + 1$	
9	$A - 3R$	$10R + 3$	$n = 0, 1, \ldots, 2R + 1$	

As an example consider 7519. Using tables on preceding pages proceed as follows:

Step I

From Table $N = 7519$; $A = 751$; $R = 8$, $K = 743$; $P_1 = 89$ and the series obtained:

743	89
744	79
745	69
746	59
751	9
752	1
753	11
760	81

Examining the Table of Factors and Primes beginning with 743 note whether 743 has 89 as a factor; whether 744 has 79 as a factor, etc. Then continue to read from left to right keeping in mind the possible factors 69, 59, . . . 81.

Since none are found one concludes that 7519 has no factors within the given range ending in 9 or 1.

Step II

From Table $K = 727$ and $P_1 = 83$; the series obtained is:

727	83
730	73
733	63
—	—
751	3
754	7
—	—
778	87

Proceed exactly as in Step I. Begin with 727 and note whether it has 83 as a factor. Thereafter examine every *third* entry for the remaining corresponding possible factors 73, 63 . . . 3, 7, . . . 87. Since 730 yields the factor 73 one concludes that 73 is the factor of 7519. By division $7519 = 73 \times 103$. Had no factor been found in either Step I or Step II the conclusion would be that the number under consideration was prime.

Proof for Step I

Let N end in 1. Then, if N has a factor ending in 1, write

$$(10a + 1)(10b + 1) = N = 10A + 1$$
$$10ab + a + b = A$$

or

$$b(10a + 1) = (A - a)$$

This proves that any factor $10a + 1$ of N is also a factor of $A - a$. Let $a = (R - n)$, then $(10a + 1)$ becomes $(10R + 1) - 10n$ and $(A - a)$ becomes $(A - R) + n$, i.e., $P_1 - 10n$ and $K + n$ respectively as given in the table. Since $P_1 - 10n$ becomes a number ending in 9 when $P_1 < 10n$, all possible factors ending in 9 are also provided for.

The proof for Step II is similar. For possible factors ending in 3 or 7 write

$$(10a + 7)(10b + 3) = N = 10A + 1.$$

By identical reasoning this results in $P_1 - 10n$ and $K + 3n$ respectively given in the table. This completes the proof for numbers ending in 1.

Identical reasoning establishes the key numbers and series for ending in 3, 7, or 9.

*Derivatives

In the following formulas u, v, w represent functions of x, while a, c, n represent fixed real numbers. All arguments in the trigonometric functions are measured in radians, and all inverse trigonometric and hyperbolic functions represent principal values.

1. $\dfrac{d}{dx}(a) = 0$

2. $\dfrac{d}{dx}(x) = 1$

3. $\dfrac{d}{dx}(au) = a\dfrac{du}{dx}$

4. $\dfrac{d}{dx}(u + v - w) = \dfrac{du}{dx} + \dfrac{dv}{dx} - \dfrac{dw}{dx}$

5. $\dfrac{d}{dx}(uv) = u\dfrac{dv}{dx} + v\dfrac{du}{dx}$

6. $\dfrac{d}{dx}(uvw) = uv\dfrac{dw}{dx} + vw\dfrac{du}{dx} + uw\dfrac{dv}{dx}$

7. $\dfrac{d}{dx}\left(\dfrac{u}{v}\right) = \dfrac{v\dfrac{du}{dx} - u\dfrac{dv}{dx}}{v^2} = \dfrac{1}{v}\dfrac{du}{dx} - \dfrac{u}{v^2}\dfrac{dv}{dx}$

8. $\dfrac{d}{dx}(u^n) = nu^{n-1}\dfrac{du}{dx}$

9. $\dfrac{d}{dx}(\sqrt{u}) = \dfrac{1}{2\sqrt{u}}\dfrac{du}{dx}$

10. $\dfrac{d}{dx}\left(\dfrac{1}{u}\right) = -\dfrac{1}{u^2}\dfrac{du}{dx}$

11. $\dfrac{d}{dx}[f(u)] = \dfrac{d}{du}[f(u)] \cdot \dfrac{du}{dx}$

12. $\dfrac{d^2}{dx^2}[f(u)] = \dfrac{df(u)}{du} \cdot \dfrac{d^2u}{dx^2} + \dfrac{d^2f(u)}{du^2} \cdot \left(\dfrac{du}{dx}\right)^2$

13. $\dfrac{d^n}{dx^n}[uv] = \binom{n}{0} v\dfrac{d^nu}{dx^n} + \binom{n}{1}\dfrac{dv}{dx}\dfrac{d^{n-1}u}{dx^{n-1}} + \binom{n}{2}\dfrac{d^2v}{dx^2}\dfrac{d^{n-2}u}{dx^{n-2}}$
$+ \cdots + \binom{n}{k}\dfrac{d^kv}{dx^k}\dfrac{d^{n-k}u}{dx^{n-k}} + \cdots + \binom{n}{n} u\dfrac{d^nv}{dx^n}$

where $\binom{n}{r} = \dfrac{n!}{r!(n-r)!}$ the binomial coefficient, n non-negative integer and $\binom{n}{0} = 1$.

14. $\dfrac{du}{dx} = \dfrac{1}{\dfrac{dx}{du}}$ if $\dfrac{dx}{du} \neq 0$

* Let $y = f(x)$ and $\dfrac{dy}{dx} = \dfrac{d[f(x)]}{dx} = f'(x)$ define respectively a function and its derivative for any value x in their common domain. The differential for the function at such a value x is accordingly defined as

$$dy = d[f(x)] = \frac{dy}{dx}\,dx = \frac{d[f(x)]}{dx}\,dx = f'(x)\,dx$$

Each derivative formula has an associated differential formula. For example, formula 6 above has the differential formula

$$d(uvw) = uv\,dw + vw\,du + uw\,dv$$

15. $\frac{d}{dx}(\log_a u) = (\log_a e)\frac{1}{u}\frac{du}{dx}$

16. $\frac{d}{dx}(\log_e u) = \frac{1}{u}\frac{du}{dx}$

17. $\frac{d}{dx}(a^u) = a^u(\log_e a)\frac{du}{dx}$

18. $\frac{d}{dx}(e^u) = e^u\frac{du}{dx}$

19. $\frac{d}{dx}(u^v) = vu^{v-1}\frac{du}{dx} + (\log_e u)u^v\frac{dv}{dx}$

20. $\frac{d}{dx}(\sin u) = \frac{du}{dx}(\cos u)$

21. $\frac{d}{dx}(\cos u) = -\frac{du}{dx}(\sin u)$

22. $\frac{d}{dx}(\tan u) = \frac{du}{dx}(\sec^2 u)$

23. $\frac{d}{dx}(\cot u) = -\frac{du}{dx}(\csc^2 u)$

24. $\frac{d}{dx}(\sec u) = \frac{du}{dx}\sec u \cdot \tan u$

25. $\frac{d}{dx}(\csc u) = -\frac{du}{dx}\csc u \cdot \cot u$

26. $\frac{d}{dx}(\text{vers } u) = \frac{du}{dx}\sin u$

27. $\frac{d}{dx}(\arcsin u) = \frac{1}{\sqrt{1-u^2}} \cdot \frac{du}{dx}, \left(-\frac{\pi}{2} \leq \arcsin u \leq \frac{\pi}{2}\right)$

28. $\frac{d}{dx}(\arccos u) = -\frac{1}{\sqrt{1-u^2}}\frac{du}{dx}, (0 \leq \arccos u \leq \pi)$

29. $\frac{d}{dx}(\arctan u) = \frac{1}{1+u^2}\frac{du}{dx}, \left(-\frac{\pi}{2} < \arctan u < \frac{\pi}{2}\right)$

30. $\frac{d}{dx}(\operatorname{arccot} u) = -\frac{1}{1+u^2}\frac{du}{dx}, (0 \leq \operatorname{arccot} u \leq \pi)$

31. $\frac{d}{dx}(\operatorname{arcsec} u) = \frac{1}{u\sqrt{u^2-1}}\frac{du}{dx}, \left(0 \leq \operatorname{arcsec} u < \frac{\pi}{2}, -\pi \leq \operatorname{arcsec} u < -\frac{\pi}{2}\right)$

32. $\frac{d}{dx}(\operatorname{arccsc} u) = -\frac{1}{u\sqrt{u^2-1}}\frac{du}{dx}, \left(0 < \operatorname{arccsc} u \leq \frac{\pi}{2}, -\pi < \operatorname{arccsc} u \leq -\frac{\pi}{2}\right)$

33. $\frac{d}{dx}(\text{arc vers } u) = \frac{1}{\sqrt{2u-u^2}}\frac{du}{dx}, (0 \leq \text{arc vers } u \leq \pi)$

34. $\frac{d}{dx}(\sinh u) = \frac{du}{dx}(\cosh u)$

35. $\frac{d}{dx}(\cosh u) = \frac{du}{dx}(\sinh u)$

36. $\frac{d}{dx}(\tanh u) = \frac{du}{dx}(\operatorname{sech}^2 u)$

37. $\frac{d}{dx}(\coth u) = -\frac{du}{dx}(\operatorname{csch}^2 u)$

38. $\frac{d}{dx}(\operatorname{sech} u) = -\frac{du}{dx}(\operatorname{sech} u \cdot \tanh u)$

39. $\frac{d}{dx}(\operatorname{csch} u) = -\frac{du}{dx}(\operatorname{csch} u \cdot \coth u)$

40. $\dfrac{d}{dx}(\sinh^{-1} u) = \dfrac{d}{dx}[\log (u + \sqrt{u^2 + 1})] = \dfrac{1}{\sqrt{u^2 + 1}} \dfrac{du}{dx}$

41. $\dfrac{d}{dx}(\cosh^{-1} u) = \dfrac{d}{dx}[\log (u + \sqrt{u^2 - 1})] = \dfrac{1}{\sqrt{u^2 - 1}} \dfrac{du}{dx}$, $(u > 1, \cosh^{-1} u > 0)$

42. $\dfrac{d}{dx}(\tanh^{-1} u) = \dfrac{d}{dx}\left[\dfrac{1}{2} \log \dfrac{1 + u}{1 - u}\right] = \dfrac{1}{1 - u^2} \dfrac{du}{dx}$, $(u^2 < 1)$

43. $\dfrac{d}{dx}(\coth^{-1} u) = \dfrac{d}{dx}\left[\dfrac{1}{2} \log \dfrac{u + 1}{u - 1}\right] = \dfrac{1}{1 - u^2} \dfrac{du}{dx}$, $(u^2 > 1)$

44. $\dfrac{d}{dx}(\operatorname{sech}^{-1} u) = \dfrac{d}{dx}\left[\log \dfrac{1 + \sqrt{1 - u^2}}{u}\right] = -\dfrac{1}{u\sqrt{1 - u^2}} \dfrac{du}{dx}$, $(0 < u < 1)$

45. $\dfrac{d}{dx}(\operatorname{csch}^{-1} u) = \dfrac{d}{dx}\left[\log \dfrac{1 + \sqrt{1 + u^2}}{u}\right] = -\dfrac{1}{|u|\sqrt{1 + u^2}} \dfrac{du}{dx}$

46. $\dfrac{d}{dq} \displaystyle\int_p^q f(x)\, dx = f(q)$, [$p$ constant]

47. $\dfrac{d}{dp} \displaystyle\int_p^q f(x)\, dx = -f(p)$, [$q$ constant]

48. $\dfrac{d}{da} \displaystyle\int_p^q f(x, a)\, dx = \int_p^q \frac{\partial}{\partial a}[f(x, a)]\, dx + f(q, a) \frac{dq}{da} - f(p, a) \frac{dp}{da}$

INTEGRATION

The following is a brief discussion of some integration techniques. A more complete discussion can be found in a number of good text books. However, the purpose of this introduction is simply to discuss a few of the important techniques which may be used, in conjunction with the integral table which follows, to integrate particular functions.

No matter how extensive the integral table, it is a fairly uncommon occurrence to find in the table the exact integral desired. Usually some form of transformation will have to be made. The simplest type of transformation, and yet the most general, is substitution. Simple forms of substitution, such as $y = ax$, are employed almost unconsciously by experienced users of integral tables. Other substitutions may require more thought. In some sections of the tables, appropriate substitutions are suggested for integrals which are similar to, but not exactly like, integrals in the table. Finding the right substitution is largely a matter of intuition and experience.

Several precautions must be observed when using substitutions:

1. Be sure to make the substitution in the dx term, as well as everywhere else in the integral.
2. Be sure that the function substituted is one-to-one and continuous. If this is not the case, the integral must be restricted in such a way as to make it true. See the example following.
3. With definite integrals, the limits should also be expressed in terms of the new dependent variable. With indefinite integrals, it is necessary to perform the reverse substitutions to obtain the answer in terms of the original independent variable. This may also be done for definite integrals, but it is usually easier to change the limits.

Example:

$$\int \frac{x^4}{\sqrt{a^2 - x^2}}\, dx$$

Here we make the substitution $x = |a| \sin\theta$. Then $dx = |a| \cos\theta d\theta$, and

$$\sqrt{a^2 - x^2} = \sqrt{a^2 - a^2 \sin^2\theta} = |a| \sqrt{1 - \sin^2\theta} = |a \cos\theta|$$

Notice the absolute value signs. It is very important to keep in mind that a square root radical always denotes the positive square root, and to assure the sign is always kept positive. Thus $\sqrt{x^2} = |x|$. Failure to observe this is a common cause of errors in integration.

Notice also that the indicated substitution is not a one-to-one function, that is, it does not have a unique inverse. Thus we must restrict the range of θ in such a way as to make the function one-to-one. Fortunately, this is easily done by solving for θ

$$\theta = \sin^{-1} \frac{x}{|a|}$$

and restricting the inverse sine to the principal values, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$.

Thus the integral becomes

$$\int \frac{a^4 \sin^4\theta\, |a| \cos\theta d\theta}{|a|\, |\cos\theta|}$$

Now, however, in the range of values chosen for θ, $\cos\theta$ is always positive. Thus we may remove the absolute value signs from $\cos\theta$ in the denominator. (This is one of the reasons that the principal values of the inverse trigonometric functions are defined as they are.)

Then the $\cos\theta$ terms cancel, and the integral becomes

$$a^4 \int \sin^4\theta \, d\theta$$

By application of integral formulas 244 and 242, we integrate this to

$$-a^4 \frac{\sin^3\theta \cos\theta}{4} - \frac{3a^4}{8}\cos\theta \sin\theta + \frac{3a^4}{8}\theta + C$$

We now must perform the inverse substitution to get the result in terms of x. We have

$$\theta = \sin^{-1}\frac{x}{|a|}$$

$$\sin\theta = \frac{x}{|a|}$$

Then

$$\cos\theta = \pm\sqrt{1 - \sin^2\theta} = \pm\sqrt{1 - \frac{x^2}{a^2}} = \pm\frac{\sqrt{a^2 - x^2}}{|a|}.$$

Because of the previously mentioned fact that $\cos\theta$ is positive, we may omit the $\pm$ sign. The reverse substitution then produces the final answer

$$\int \frac{x^4}{\sqrt{a^2 - x^2}}\,dx = -\tfrac{1}{4}x^3\sqrt{a^2 - x^2} - \tfrac{3}{8}a^2 x\sqrt{a^2 - x^2} + \frac{3a^4}{8}\sin^{-1}\frac{x}{|a|} + C.$$

Any rational function of x may be integrated, if the denominator is factored into linear and irreducible quadratic factors. The function may then be broken into partial fractions, and the individual partial fractions integrated by use of the appropriate formula from the integral table. See the section on partial fractions for further information.

Many integrals may be reduced to rational functions by proper substitutions. For example,

$$z = \tan\frac{x}{2}$$

will reduce any rational function of the six trigonometric functions of x to a rational function of z. (Frequently there are other substitutions which are simpler to use, but this one will always work. See integral formula number 374.)

Any rational function of x and $\sqrt{ax + b}$ may be reduced to a rational function of z by making the substitution

$$z = \sqrt{ax + b}.$$

Other likely substitutions will be suggested by looking at the form of the integrand.

The other main method of transforming integrals is integration by parts. This involves applying formula number 5 or 6 in the accompanying integral table. The critical factor in this method is the choice of the functions u and v. In order for the method to be successful, $v = \int dv$ and $\int v\,du$ must be easier to integrate than the original integral. Again, this choice is largely a matter of intuition and experience.

Example:

$$\int x \sin x\,dx$$

Two obvious choices are $u = x$, $dv = \sin x\,dx$, or $u = \sin x$, $dv = x\,dx$. Since a preliminary mental calculation indicates that $\int v\,du$ in the second choice would be more,

rather than less, complicated than the original integral (it would contain x^2), we use the first choice.

$$u = x \qquad du = dx$$

$$dv = \sin x\, dx \qquad v = -\cos x$$

$$\int x \sin x\, dx = \int u\, dv = uv - \int v\, du = -x \cos x + \int \cos x\, dx$$

$$= \sin x - x \cos x$$

Of course, this result could have been obtained directly from the integral table, but it provides a simple example of the method. In more complicated examples the choice of u and v may not be so obvious, and several different choices may have to be tried. Of course, there is no guarantee that any of them will work.

Integration by parts may be applied more than once, or combined with substitution. A fairly common case is illustrated by the following example.

Example:

$$\int e^x \sin x\, dx$$

Let $u = e^x$ Then $du = e^x\, dx$

$dv = \sin x\, dx$ $v = -\cos x$

$$\int e^x \sin x\, dx = \int u\, dv = uv - \int v\, du = -e^x \cos x + \int e^x \cos x\, dx$$

In this latter integral,

let $u = e^x$ Then $du = e^x\, dx$

$dv = \cos x\, dx$ $v = \sin x$

$$\int e^x \sin x\, dx = -e^x \cos x + \int e^x \cos x\, dx = -e^x \cos x + \int u\, dv$$

$$= -e^x \cos x + uv - \int v\, du$$

$$= -e^x \cos x + e^x \sin x - \int e^x \sin x\, dx$$

This looks as if a circular transformation has taken place, since we are back at the same integral we started from. However, the above equation can be solved algebraically for the required integral:

$$\int e^x \sin x\, dx = \tfrac{1}{2}(e^x \sin x - e^x \cos x)$$

In the second integration by parts, if the parts had been chosen as $u = \cos x$, $dv = e^x\, dx$, we would indeed have made a circular transformation, and returned to the starting place. In general, when doing repeated integration by parts, one should never choose the function u at any stage to be the same as the function v at the previous stage, or a constant times the previous v.

The following rule is called the extended rule for integration by parts. It is the result of $n + 1$ successive applications of integration by parts.

If

$$g_1(x) = \int g(x)\, dx, \qquad g_2(x) = \int g_1(x)\, dx,$$

$$g_3(x) = \int g_2(x)\, dx, \ldots, g_m(x) = \int g_{m-1}(x)\, dx, \ldots,$$

then

$$\int f(x) \cdot g(x)\, dx = f(x) \cdot g_1(x) - f'(x) \cdot g_2(x) + f''(x) \cdot g_3(x) - + \cdots$$

$$+ (-1)^n f^{(n)}(x)\, g_{n+1}(x) + (-1)^{n+1} \int f^{(n+1)}(x)\, g_{n+1}(x)\, dx.$$

A useful special case of the above rule is when $f(x)$ is a polynomial of degree n. Then $f^{(n+1)}(x) = 0$, and

$$\int f(x)\cdot g(x)\,dx = f(x)\cdot g_1(x) - f'(x)\cdot g_2(x) + f''(x)\cdot g_3(x) - + \cdots + (-1)^n f^{(n)}(x) g_{n+1}(x) + C$$

Example:

If $f(x) = x^2$, $g(x) = \sin x$

$$\int x^2 \sin x\,dx = -x^2 \cos x + 2x \sin x + 2\cos x + C$$

Another application of this formula occurs if

$$f''(x) = af(x) \quad \text{and} \quad g''(x) = bg(x),$$

where a and b are unequal constants. In this case, by a process similar to that used in the above example for $\int e^x \sin x\,dx$, we get the formula

$$f(x)g(x)\,dx = \frac{f(x)\cdot g'(x) - f'(x)\cdot g(x)}{b - a} + C$$

This formula could have been used in the example mentioned. Here is another example.

Example:

If $f(x) = e^{2x}$, $g(x) = \sin 3x$, then $a = 4$, $b = -9$, and

$$\int e^{2x} \sin 3x\,dx = \frac{3e^{2x}\cos 3x - 2e^{2x}\sin 3x}{-9 - 4} + C = \frac{e^{2x}}{13}(2\sin 3x - 3\cos 3x) + C$$

The following additional points should be observed when using this table.

1. A constant of integration is to be supplied with the answers for indefinite integrals.
2. Logarithmic expressions are to base $e = 2.71828\ldots$, unless otherwise specified, and are to be evaluated for the absolute value of the arguments involved therein.
3. All angles are measured in radians, and inverse trigonometric and hyperbolic functions represent principal values, unless otherwise indicated.
4. If the application of a formula produces either a zero denominator or the square root of a negative number in the result, there is always available another form of the answer which avoids this difficulty. In many of the results, the excluded values are specified, but when such are omitted it is presumed that one can tell what these should be, especially when difficulties of the type herein mentioned are obtained.
5. When inverse trigonometric functions occur in the integrals, be sure that any replacements made for them are strictly in accordance with the rules for such functions. This causes little difficulty when the argument of the inverse trigonometric function is positive, since then all angles involved are in the first quadrant. However, if the argument is negative, special care must be used. Thus if $u > 0$,

$$\sin^{-1} u = \cos^{-1}\sqrt{1 - u^2} = \csc^{-1}\frac{1}{u}, \text{ etc.}$$

However, if $u < 0$,

$$\sin^{-1} u = -\cos^{-1}\sqrt{1 - u^2} = -\pi - \csc^{-1}\frac{1}{u}, \text{ etc.}$$

See the section on inverse trigonometric functions for a full treatment of the allowable substitutions.

6. In integrals 259–263, the right side includes expressions of the form

$$A\tan^{-1}[B + C\tan f(x)].$$

In these formulas, the $\tan^{-1}$ does not necessarily represent the principal value. Instead of always employing the principal branch of the inverse tangent function, one must instead use that branch of the inverse tangent function upon which $f(x)$ lies for any particular choice of x.

Example:

Using Integral Formula 259.

$$\int_0^{4\pi} \frac{dx}{2 + \sin x} = \frac{2}{\sqrt{3}} \tan^{-1} \frac{2 \tan \frac{x}{2} + 1}{\sqrt{3}} \Bigg]_0^{4\pi}$$

$$= \frac{2}{\sqrt{3}} \left[\tan^{-1} \frac{2 \tan 2\pi + 1}{\sqrt{3}} - \tan^{-1} \frac{2 \tan 0 + 1}{\sqrt{3}} \right]$$

$$= \frac{2}{\sqrt{3}} \left[\frac{13\pi}{6} - \frac{\pi}{6} \right] = \frac{4\pi}{\sqrt{3}} = \frac{4\sqrt{3}\pi}{3}$$

Here

$$\tan^{-1} \frac{2 \tan 2\pi + 1}{\sqrt{3}} = \tan^{-1} \frac{1}{\sqrt{3}} = \frac{13\pi}{6},$$

since $f(x) = 2\pi$; and

$$\tan^{-1} \frac{2 \tan 0 + 1}{\sqrt{3}} = \tan^{-1} \frac{1}{\sqrt{3}} = \frac{\pi}{6},$$

since $f(x) = 0$.

ELEMENTARY FORMS

1. $\int a\,dx = ax$

2. $\int a \cdot f(x)dx = a\int f(x)dx$

3. $\int \phi(y)\,dx = \int \frac{\phi(y)}{y'}\,dy, \qquad \text{where } y' = \frac{dy}{dx}$

4. $\int (u+v)\,dx = \int u\,dx + \int v\,dx$, where u and v are any functions of x

5. $\int u\,dv = u\int dv - \int v\,du = uv - \int v\,du$

6. $\int u\frac{dv}{dx}\,dx = uv - \int v\frac{du}{dx}\,dx$

7. $\int x^n\,dx = \frac{x^{n+1}}{n+1}, \qquad \text{except } n = -1$

8. $\int \frac{f'(x)\,dx}{f(x)} = \log f(x), \qquad (df(x) = f'(x)\,dx)$

9. $\int \frac{dx}{x} = \log x$

10. $\int \frac{f'(x)\,dx}{2\sqrt{f(x)}} = \sqrt{f(x)}, \qquad (df(x) = f'(x)\,dx)$

11. $\int e^x\,dx = e^x$

12. $\int e^{ax}\,dx = e^{ax}/a$

13. $\int b^{ax}\,dx = \frac{b^{ax}}{a\log b}, \ (b > 0)$

14. $\int \log x\,dx = x\log x - x$

15. $\int a^x \log a\,dx = a^x, \ (a > 0)$

16. $\int \frac{dx}{a^2+x^2} = \frac{1}{a}\tan^{-1}\frac{x}{a}$

17. $\int \frac{dx}{a^2-x^2} = \begin{cases} \frac{1}{a}\tanh^{-1}\frac{x}{a} \\ \text{or} \\ \frac{1}{2a}\log\frac{a+x}{a-x}, & (a^2 > x^2) \end{cases}$

18. $$\int \frac{dx}{x^2 - a^2} = \begin{cases} -\frac{1}{a} \coth^{-1} \frac{x}{a} \\ \text{or} \\ \frac{1}{2a} \log \frac{x - a}{x + a}, \qquad (x^2 > a^2) \end{cases}$$

* For large positive values of x, $\Gamma(x)$ approximates the asymptotic series

$$x^{x-\frac{1}{2}}e^{-x}\sqrt{\frac{2\pi}{x}}\left[1+\frac{1}{12x}+\frac{1}{288x^2}-\frac{139}{51840x^3}-\frac{571}{2488320x^4}+\cdots\right].$$

BESSEL FUNCTIONS $J_0(x)$ AND $J_1(x)$

$$J_0(x) = 1-\left(\frac{x}{2}\right)^2+\frac{\left(\frac{x}{2}\right)^4}{1^2\cdot 2^2}-\frac{\left(\frac{x}{2}\right)^6}{1^2\cdot 2^2\cdot 3^2}+-\cdots$$

$$J_1(x) = -J_0'(x) = \frac{x}{2}-\frac{\left(\frac{x}{2}\right)^3}{1^2\cdot 2}+\frac{\left(\frac{x}{2}\right)^5}{1^2\cdot 2^2\cdot 3}-+\cdots.$$

$$J_n(x) = \sum_{k=0}^{\infty}\frac{(-1)^k X^{n+2k}}{2^{n+2k}k!(n+k)!} \qquad (n = 0, 1, 2, 3, \ldots)$$

LAPLACE TRANSFORMS

These tables of Operations and Transforms were taken from "Modern Operational Mathematics in Engineering" by permission from the author, R. V. Churchill, and the publisher, McGraw-Hill Book Company, Inc.

The operational method for solving differential equations makes use of the Laplace transformation which associates a given function $F(t)$ with a second function $f(s)$, so that

$$f(s) = L\{F(t)\} = \int_0^\infty e^{-st}F(t)\,dt,$$

where t = a real variable, $F(t)$ = a real function of t; $F(t) = 0$, $t < 0$; $f(s)$ = a function of s; s = a complex variable; and $e = 2.71828\ldots$.

$f(s)$ is called the Laplace transform of $F(t)$.

$F(t)$ can also be expressed as follows:

$$F(t) = \frac{1}{2\pi i}\int_{a-i\infty}^{a+i\infty} e^{st}f(s)\,ds,$$

where a is chosen to the right of any singularity of $f(s)$.

FOURIER TRANSFORMS

For a sectionally continuous function $F(x)$ over a finite interval of the variable x, in which the origin and a unit of length have been so chosen that the end points of the interval for x become $x = 0$ and $x = \pi$, the Fourier finite sine and cosine transforms for $F(x)$ are defined and symbolized respectively as follows:

$$S\{F(x)\} = \int_0^\pi F(x)\sin nx\,dx = f_s(n) \qquad (n = 1, 2, \cdots)$$

$$C\{F(x)\} = \int_0^\pi F(x)\cos nx\,dx = f_c(n) \qquad (n = 1, 2, \cdots)$$

If the interval for $F(x)$ is defined so that the end points are $x = 0$ and $x = l$, the substitution $\alpha = \frac{\pi x}{l}$ makes possible the use of these tables with

$$\int_0^l F(x)\sin\frac{n\pi x}{l}\,dx = \frac{l}{\pi}S\left\{F\left(\frac{lx}{\pi}\right)\right\}$$

$$\int_0^l F(x)\cos\frac{nx}{l}\,dx = \frac{l}{\pi}C\left\{F\left(\frac{lx}{\pi}\right)\right\}$$

Thus if $F(x) = x$ for interval $(0,l)$

$$\int_0^l x\sin\frac{n\pi x}{l}\,dx = \frac{l}{\pi}S\left\{\frac{l}{\pi}x\right\} = \frac{l^2}{\pi^2}S\{x\} = \frac{l^2}{\pi^2}\frac{(-1)^{n+1}}{n} \qquad (n = 1, 2, \cdots)$$

* $K_n(x)$ is Bessel's function of the second kind for the imaginary argument.

* Several additional transforms, especially those involving other Bessel functions, can be found in the tables by G. A. Campbell and R. M. Foster, "Fourier Integrals for Practical Applications," or N. W. McLachlan and P. Humbert, "Formulaire pour le calcul symbolique." In the tables by Campbell and Foster, only those entries containing the condition $0 < \varrho$ or $k < \varrho$, where ϱ is our t, are Laplace transforms.

14	0 when $n = 1, 2, \cdots$; $f_c(m) = \frac{\pi}{2}$ $(m = 1, 2, \cdots)$	$\cos mx$

The following functions appear among the entries of the preceding tables on transforms.

Function	Definition	Name
$Ei(x)$	$\int_{-\infty}^{x} \frac{e^v}{v} dv$; or sometimes defined as $-Ei(-x) = \int_x^\infty \frac{e^{-v}}{v} dv$	See index for Sine, Cosine, and Exponential Integral tables
$Si(x)$	$\int_0^x \frac{\sin v}{v} dv$	See index for Sine, Cosine, and Exponential Integral tables
$Ci(x)$	$\int_\infty^x \frac{\cos v}{v} dv$; or sometimes defined as negative of this integral	See index for Sine, Cosine, and Exponential Integral tables
$erf(x)$	$\frac{2}{\sqrt{\pi}} \int_0^x e^{-v^2} dv$	Error function
$erfc(x)$	$1 - erf(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-v^2} dv$	Complementary function to error function
$L_n(x)$	$\frac{e^x}{n!} \frac{d^n}{dx^n}(x^n e^{-x})$, $n = 0, 1, \cdots$	Laguerre polynomial of degree n

Special Formulas

Certain types of differential equations occur sufficiently often to justify the use of formulas for the corresponding particular solutions. The following set of tables I to XIV covers all first-second and n'th order ordinary linear differential equations with constant coefficients for which the right members are of the form $P(x)e^{rx}\sin sx$ or $P(x)e^{rx}\cos sx$ where r and s are constants and $P(x)$ is a polynomial of degree n.

When the right member of a reducible partial linear differential equation with constant coefficients is not zero, particular solutions for certain types of right members are contained in tables XV to XXI. In these tables both F and P are used to denote polynomials, and it is assumed that no denominator is zero. In any formula the roles of x and y may be reversed throughout, changing a formula in which x dominates to one in which y dominates. Tables XIX, XX, XXI are applicable whether the equations are reducible or not. The symbol $\binom{m}{n}$ stands for $\dfrac{m!}{(m-n)!n!}$ and is the $n+1$ st coefficient in the expansion of $(a+b)^m$. Also $0! = 1$ by definition.

The tables as herewith given are those contained in the text Differential Equations by Ginn and Company (1955) and are published with their kind permission and that of the author, Professor Frederick H. Steen.

TABLE I: $(D-a)y = R$

R	y_p
1. e^{rx}	$\dfrac{e^{rx}}{r-a}$
2. $\sin sx$*	$-\dfrac{a\sin sx + s\cos sx}{a^2+s^2} = -\dfrac{1}{\sqrt{a^2+s^2}}\sin\left(sx+\tan^{-1}\dfrac{s}{a}\right)$
3. $P(x)$	$-\dfrac{1}{a}\left[P(x)+\dfrac{P'(x)}{a}+\dfrac{P''(x)}{a^2}+\cdots+\dfrac{P^{(n)}(x)}{a^n}\right]$
4. $e^{rx}\sin sx$*	Replace a by $a-r$ in formula 2 and multiply by e^{rx}.
5. $P(x)e^{rx}$	Replace a by $a-r$ in formula 3 and multiply by e^{rx}.
6. $P(x)\sin sx$*	$-\sin sx\left[\dfrac{a}{a^2+s^2}P(x)+\dfrac{a^2-s^2}{(a^2+s^2)^2}P'(x)+\dfrac{a^3-3as^2}{(a^2+s^2)^3}P''(x)+\cdots+\dfrac{a^k-\binom{k}{2}a^{k-2}s^2+\binom{k}{4}a^{k-4}s^4-\cdots}{(a^2+s^2)^k}P^{(k-1)}(x)+\cdots\right]$ $-\cos sx\left[\dfrac{s}{a^2+s^2}P(x)+\dfrac{2as}{(a^2+s^2)^2}P'(x)+\dfrac{3a^2s-s^3}{(a^2+s^2)^3}P''(x)+\cdots+\dfrac{\binom{k}{1}a^{k-1}s-\binom{k}{3}a^{k-3}s^3+\cdots}{(a^2+s^2)^k}P^{(k-1)}(x)+\cdots\right]$
7. $P(x)e^{rx}\sin sx$*	Replace a by $a-r$ in formula 6 and multiply by e^{rx}.
8. e^{ax}	xe^{ax}
9. $e^{ax}\sin sx$*	$-\dfrac{e^{ax}\cos sx}{s}$
10. $P(x)e^{ax}$	$e^{ax}\int P(x)\,dx$
11. $P(x)e^{ax}\sin sx$*	$\dfrac{e^{ax}\sin sx}{s}\left[\dfrac{P'(x)}{s^2}-\dfrac{P'''(x)}{s^4}+\dfrac{P^{v}(x)}{s^6}-\cdots\right]-\dfrac{e^{ax}\cos sx}{s}\left[P(x)-\dfrac{P''(x)}{s^2}+\dfrac{P^{iv}(x)}{s^4}-\cdots\right]$

* For $\cos sx$ in R replace "sin" by "cos" and "cos" by "$-$ sin" in y_p.

$$D^n = \frac{d^n}{dx^n} \qquad \binom{m}{n} = \frac{m!}{(m-n)!n!} \qquad 0! = 1$$

TABLE II: $(D - a)^2 y = R$

R	y_p
12. e^{rx}	$\dfrac{e^{rx}}{(r-a)^2}$
13. $\sin sx$*	$\dfrac{1}{(a^2+s^2)^2}[(a^2-s^2)\sin sx + 2as\cos sx] = \dfrac{1}{a^2+s^2}\sin\left(sx + \tan^{-1}\dfrac{2as}{a^2-s^2}\right)$
14. $P(x)$	$\dfrac{1}{a^2}\left[P(x) + \dfrac{2P'(x)}{a} + \dfrac{3P''(x)}{a^2} + \cdots + \dfrac{(n+1)P^{(n)}(x)}{a^n}\right]$
15. $e^{rx}\sin sx$*	Replace a by $a - r$ in formula 13 and multiply by e^{rx}.
16. $P(x)e^{rx}$	Replace a by $a - r$ in formula 14 and multiply by e^{rx}.
17. $P(x)\sin sx$*	$\sin sx\left[\dfrac{a^2-s^2}{(a^2+s^2)^2}P(x) + 2\dfrac{a^3-3as^2}{(a^2+s^2)^3}P'(x) + 3\dfrac{a^4-6a^2s^2+s^4}{(a^2+s^2)^4}P''(x) + \cdots + (k-1)\dfrac{a^k - \binom{k}{2}a^{k-2}s^2 + \binom{k}{4}a^{k-4}s^4 - \cdots}{(a^2+s^2)^k}P^{(k-2)}(x) + \cdots\right]$ $+ \cos sx\left[\dfrac{2as}{(a^2+s^2)^2}P(x) + 2\dfrac{3a^2s-s^3}{(a^2+s^2)^3}P'(x) + 3\dfrac{4a^3s-4as^3}{(a^2+s^2)^4}P''(x) + \cdots + (k-1)\dfrac{\binom{k}{1}a^{k-1}s - \binom{k}{3}a^{k-3}s^3 + \cdots}{(a^2+s^2)^k}P^{(k-2)}(x) + \cdots\right]$
18. $P(x)e^{rx}\sin sx$*	Replace a by $a - r$ in formula 17 and multiply by e^{rx}.
19. e^{ax}	$\frac{1}{2}x^2e^{ax}$
20. $e^{ax}\sin sx$*	$-\dfrac{e^{ax}\sin sx}{s^2}$
21. $P(x)e^{ax}$	$e^{ax}\int\int P(x)dx\,dx$
22. $P(x)e^{ax}\sin sx$*	$-\dfrac{e^{ax}\sin sx}{s^2}\left[P(x) - \dfrac{3P''(x)}{s^2} + \dfrac{5P^{\mathrm{iv}}(x)}{s^4} - \dfrac{7P^{\mathrm{vi}}(x)}{s^5} + \cdots\right] - \dfrac{e^{ax}\cos sx}{s^2}\left[\dfrac{2P'(x)}{s} - \dfrac{4P'''(x)}{s^3} + \dfrac{6P^{\mathrm{v}}(x)}{s^5} - \cdots\right]$

TABLE III: $(D^2 + q)y = R$

R	y_p
23. e^{rx}	$\dfrac{e^{rx}}{r^2+q}$
24. $\sin sx$*	$\dfrac{\sin sx}{-s^2+q}$
25. $P(x)$	$\dfrac{1}{q}\left[P(x) - \dfrac{P''(x)}{q} + \dfrac{P^{\mathrm{iv}}(x)}{q^2} - \cdots + (-1)^k\dfrac{P^{(2k)}(x)}{q^k}\cdots\right]$

TABLE XX: $F(D_x, D_y)z = R$

89. e^{ax+by}	$\dfrac{e^{ax+by}}{F(a, b)}$]

TABLE XXI: $F(D_x^2, D_xD_y, D_y^2)z = R$

90. $\sin(ax + by)$*	$\dfrac{\sin(ax + by)}{F(-a^2, -ab, -b^2)}$

* For $\cos(ax + by)$ replace "sin" by "cos," and "cos" by "$-$ sin" in z_p.

The following examples illustrate the use of the tables.

EXAMPLE 1. Solve $(D^2 - 4)y = \sin 3x$.
Substitution of $q = -4$, $s = 3$ in formula 24 gives

$$y_p = \frac{\sin 3x}{-9 - 4},$$

wherefore the general solution is

$$y = c_1e^{2x} + c_2e^{-2x} - \frac{\sin 3x}{13}.$$

EXAMPLE 2. Obtain a particular solution of $(D^2 - 4D + 5)y = x^2e^{3x}\sin x$.

Applying formula 40 with $a = 2$, $b = 1$, $r = 3$, $s = 1$, $P(x) = x^2$, $s + b = 2$, $s - b = 0$, $a - r = -1$, $(a - r)^2 + (s + b)^2 = 5$, $(a - r)^2 + (s - b)^2 = 1$, we have

$$y_p = \frac{e^{3x}\sin x}{2}\left[\left(\frac{2}{5} - \frac{0}{1}\right)x^2 + \left(\frac{2\cdot -1\cdot 2}{25} - \frac{2\cdot -1\cdot 0}{1}\right)2x + \left(\frac{3\cdot 1\cdot 2 - 2^3}{125} - \frac{3\cdot 1\cdot 0 - 0}{1}\right)2\right]$$
$$- \frac{e^{3x}\cos x}{2}\left[\left(\frac{-1}{5} - \frac{-1}{1}\right)x^2 + \left(\frac{1-4}{25} - \frac{1-0}{1}\right)2x + \left(\frac{-1-3\cdot -1\cdot 4}{125} - \frac{-1-3\cdot -1\cdot 0}{1}\right)2\right]$$
$$= (\tfrac{1}{5}x^2 - \tfrac{4}{25}x - \tfrac{2}{125})e^{3x}\sin x + (-\tfrac{2}{5}x^2 + \tfrac{22}{25}x - \tfrac{136}{125})e^{3x}\cos x.$$

The special formulas effect a very considerable saving of time in problems of this type.

EXAMPLE 3. Obtain a particular solution of $(D^2 - 4D + 5)y = x^2e^{2x}\cos x$. (Compare with Example 2.)

Formula 40 is not applicable here since for this equation $r = a$, $s = b$, wherefore the denominator $(a - r)^2 + (s - b)^2 = 0$. We turn instead to formula 44. Substituting $a = 2$, $b = 1$, $P(x) = x^2$ and replacing sin by cos, cos by $-$ sin, we obtain

$$y_p = \frac{e^{2x}\cos x}{4}(x^2 - \tfrac{2}{4}) + \frac{e^{2x}\sin x}{2}\int(x^2 - \tfrac{1}{2})dx$$
$$= \left(\frac{x^2}{4} - \frac{1}{8}\right)e^{2x}\cos x + \left(\frac{x^3}{6} - \frac{x}{4}\right)e^{2x}\sin x,$$

which is the required solution.

EXAMPLE 4. Find z_p for $(D_x - 3D_y)z = \ln(y + 3x)$.
Referring to Table XV we note that formula 69 (not 68) is applicable. This gives

$$z_p = x\ln(y + 3x).$$

It is easily seen that $-\frac{y}{3}\ln(y + 3x)$ would serve equally well.

EXAMPLE 5. Solve $(D_x + 2D_y - 4)z = y\cos(y - 2x)$.
Since R in formula 76 contains a polynomial in x, not y, we rewrite the given equation in the form

$$(D_y + \tfrac{1}{2}D_x - 2)z = \tfrac{1}{2}y\cos(y - 2x).$$

Then $z_c = e^{2y}F(x - \frac{1}{2}y) = e^{2y}f(2x - y)$,

and by the formula

$$z_p = -\tfrac{1}{2}\cos(y - 2x)\cdot\left(\frac{y}{2} + \frac{\frac{1}{2}}{2}\right)$$
$$= -\tfrac{1}{8}(2y + 1)\cos(y - 2x).$$

EXAMPLE 6. Find z_p for $(D_x + 4D_y)^3z = (2x - y)^2$.
Using formula 79, we obtain

$$z_p = \frac{\int\int\int u^2du^3}{[2 + 4(-1)]^3} = \frac{u^5}{5\cdot 4\cdot 3\cdot(-8)} = -\frac{(2x - y)^5}{480}.$$

EXAMPLE 7. Find z_p for $(D_x^3 + 5D_x^2D_y - 7D_x + 4)z = e^{2x+3y}$.
By formula 87

$$z_p = \frac{e^{2x+3y}}{2^3 + 5\cdot 2^2\cdot 3 - 7\cdot 2 + 4} = \frac{e^{2x+3y}}{58}.$$

EXAMPLE 8. Find z_p for

$$(D_x^4 + 6D_x^3D_y + D_xD_y + D_y^2 + 9)z = \sin(3x + 4y).$$

Since every term in the left member is of *even* degree in the two operators D_x and D_y, formula 90 is applicable.
It gives

$$z_p = \frac{\sin(3x + 4y)}{(-9)^2 + 6(-9)(-12) + (-12) + (-16) + 9}$$
$$= \frac{\sin(3x + 4y)}{710}$$

$(a + b + c)^2 = a^2 + b^2 + c^2 + 2ab + 2ac + 2bc.$
$(a + b + c)^3 = a^3 + b^3 + c^3 + 3a^2(b + c) + 3b^2(a + c) + 3c^2(a + b) + 6abc.$
$(a + b + c + d + \ldots)^2 = a^2 + b^2 + c^2 + d^2 + \ldots + 2a(b + c + d + \ldots) + 2b(c + d + \ldots) + 2c(d + \ldots) + \ldots$

See also under Series

Powers and Roots

$a^x \times a^y = a^{(x+y)}.$ $\quad a^0 = 1$ [if $a \neq 0$]. $\quad (ab)^x = a^x b^x.$

$\dfrac{a^x}{a^y} = a^{(x-y)}.$ $\quad a^{-x} = \dfrac{1}{a^x}.$ $\quad \left(\dfrac{a}{b}\right)^x = \dfrac{a^x}{b^x}.$

$(a^x)^y = a^{xy}.$ $\quad a^{\frac{1}{x}} = \sqrt[x]{a}.$ $\quad \sqrt[x]{ab} = \sqrt[x]{a}\sqrt[x]{b}.$

$\sqrt[x]{\sqrt[y]{a}} = \sqrt[xy]{a}.$ $\quad a^{\frac{x}{y}} = \sqrt[y]{a^x}.$ $\quad \sqrt[x]{\dfrac{a}{b}} = \dfrac{\sqrt[x]{a}}{\sqrt[x]{b}}.$

Proportion

If $\dfrac{a}{b} = \dfrac{c}{d}$, then $\dfrac{a+b}{b} = \dfrac{c+d}{d}$,

$\dfrac{a-b}{b} = \dfrac{c-d}{d}$, $\dfrac{a-b}{a+b} = \dfrac{c-d}{c+d}$.

SUM OF POWERS OF INTEGERS, $\sum_{k=1}^{n} k^m$

SUMS OF NUMBERS

The sum of the first n numbers,—

$$\Sigma(n) = 1+2+3+4+5 \ldots . +n = \frac{n(n+1)}{2}$$

The sum of the squares of the first n numbers,

$$\Sigma(n^2) = 1^2+2^2+3^2+4^2+5^2 \ldots + n^2 = \frac{n(n+1)(2n+1)}{6}$$

The sum of the cubes of the first n numbers,

$$\Sigma(n^3) = 1^3+2^3+3^3+4^3+5^3 \ldots . + n^3 = \frac{n^2(n+1)^2}{4}$$

ARITHMETICAL PROGRESSION

If a is the first term; l, the last term; d, the common difference; n, the number of terms and s, the sum of n terms,—

$$l = a + (n-1)d \qquad s = \frac{n}{2}(a+l)$$

$$s = \frac{n}{2}\left\{ 2a + (n-1)d \right\}$$

GEOMETRICAL PROGRESSION

If a is the first term; l, the last term; r, the common ratio; n, the number of terms and s, the sum of n terms,—

$$l = ar^{n-1} \qquad s = a\frac{(1-r^n)}{1-r}$$

$$s = a\frac{(r^n-1)}{r-1} \qquad s = \frac{lr-a}{r-1}$$

If n is infinity and r^2 less than unity,—

$$s = \frac{a}{1-r}$$

FACTORIALS

$\underline{n} = n! = e^{-n}n^n\sqrt{2\pi n}$, approximately.

PERMUTATIONS

If M denote the number of permutations of n things taken p at a time,—

$$M = n(n-1)(n-2) \ldots . (n-p+1)$$

COMBINATIONS

If M denote the number of combinations of n things taken p at a time,—

$$M = \frac{n(n-1)(n-2) \ldots . (n-p+1)}{p!}$$

$$M = \frac{n!}{p!(n-p)!}$$

Quadratic Equations

Any quadratic equation may be reduced to the form, —

$$ax^2 + bx + c = 0$$

$$\text{Then} \quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

If a, b, and c, are real, then
if $b^2 - 4ac$ is positive, the roots are real and unequal;
if $b^2 - 4ac$ is zero, the roots are real and equal;
if $b^2 - 4ac$ is negative, the roots are imaginary and unequal;
a, b, and c, are rational.

Cubic Equations

A cubic equation, $y^3 + py^2 + qy + r = 0$ may be reduced to the form, —

$$x^3 + ax + b = 0$$

by substituting for y the value, $\left(x - \frac{p}{3}\right)$. Here

$$a = \tfrac{1}{3}(3q - p^2) \text{ and } b = \tfrac{1}{27}(2p^3 - 9pq + 27r).$$

For solution let, —

$$A = \sqrt[3]{-\frac{b}{2} + \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}}, \qquad B = \sqrt[3]{-\frac{b}{2} - \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}},$$

then the values of x will be given by,

$$x = A + B, \quad -\frac{A+B}{2} + \frac{A-B}{2}\sqrt{-3}, \quad -\frac{A+B}{2} - \frac{A-B}{2}\sqrt{-3}$$

If $\frac{b^2}{4} + \frac{a^3}{27} > 0$, there will be one real root and two conjugate imaginary roots.

If $\frac{b^2}{4} + \frac{a^3}{27} = 0$, there will be three real roots of which two at least are equal

If $\frac{b^2}{4} + \frac{a^3}{27} < 0$, there will be three real and unequal roots.

In the last case a trigonometric solution is useful. Compute the value of the angle ϕ in the expression, —

$$\cos\phi = -\frac{b}{2} \div \sqrt{\left(-\frac{a^3}{27}\right)},$$

then x will have the following values:—

$$2\sqrt{-\frac{a}{3}}\cos\frac{\phi}{3}, \qquad 2\sqrt{-\frac{a}{3}}\cos\left(\frac{\phi}{3} + 120°\right),$$

$$2\sqrt{-\frac{a}{3}}\cos\left(\frac{\phi}{3} + 240°\right)$$

PARTIAL FRACTIONS

Compiled by Professor M. D. Prince

This section applies only to rational algebraic fractions with numerator of lower degree than the denominator. Improper fractions can be reduced to proper fractions by long division.

Every fraction may be expressed as the sum of component fractions whose denominators are factors of the denominator of the original fraction.

Let $N(x)$ = numerator, a polynomial of the form

$$n_0 + n_1x + n_2x^2 + \cdots + n_ix^i$$

I. *Non-repeated Linear Factors*

$$\frac{N(x)}{(x-a)G(x)} = \frac{A}{x-a} + \frac{F(x)}{G(x)}$$

$$A = \left[\frac{N(x)}{G(x)}\right]_{x=a}$$

$F(x)$ determined by methods discussed in the following sections. Example:

$$\frac{x^2+3}{x(x-2)(x^2+2x+4)} = \frac{A}{x} + \frac{B}{x-2} + \frac{F(x)}{x^2+2x+4}$$

$$A = \left[\frac{x^2+3}{(x-2)(x^2+2x+4)}\right]_{x=0} = -\frac{3}{8}$$

$$B = \left[\frac{x^2+3}{x(x^2+2x+4)}\right]_{x=2} = \frac{4+3}{2(4+4+4)} = \frac{7}{24}$$

II. *Repeated Linear Factors*

$$\frac{N(x)}{x^mG(x)} = \frac{A_0}{x^m} + \frac{A_1}{x^{m-1}} + \cdots + \frac{A_{m-1}}{x} + \frac{F(x)}{G(x)}$$

$$F(x) = f_0 + f_1x + f_2x^2 + \cdots, \quad G(x) = g_0 + g_1x + g_2x^2 + \cdots$$

$$A_0 = \frac{n_0}{g_0}, \qquad A_1 = \frac{n_1 - A_0g_1}{g_0}, \qquad A_2 = \frac{n_2 - A_0g_2 - A_1g_1}{g_0}$$

General term: $A_k = \dfrac{1}{g_0}\left[n_k - \sum_{i=0}^{k-1} A_ig_{k-i}\right]$

$$*m = 1 \begin{cases} f_0 = n_1 - A_0g_1 \\ f_1 = n_2 - A_0g_2 \\ f_j = n_{j+1} - A_0g_{j+1} \end{cases}$$

$$m = 2 \begin{cases} f_0 = n_2 - A_0g_2 - A_1g_1 \\ f_1 = n_3 - A_0g_3 - A_1g_2 \\ f_j = n_{j+2} - [A_0g_{j+2} + A_1g_{j+1}] \end{cases}$$

$$m = 3 \begin{cases} f_0 = n_3 - A_0g_3 - A_1g_2 - A_2g_1 \\ f_1 = n_3 - A_0g_4 - A_1g_3 - A_2g_2 \\ f_j = n_{j+3} - [A_0g_{j+3} + A_1g_{j+2} + A_2g_{j+1}] \end{cases}$$

* Note: If $G(x)$ contains linear factors, $F(x)$ may be determined by previous section I.

any m: $\quad f_j = n_{m+j} - \sum_{i=0}^{m-1} A_ig_{m+j-i}$

Example: $\dfrac{x^2+1}{x^3(x^2-3x+6)} = \dfrac{A_0}{x^3} + \dfrac{A_1}{x^2} + \dfrac{A_2}{x} + \dfrac{f_1x+f_0}{x^2-3x+6}$

$$A_0 = \frac{1}{6}, \qquad A_1 = \frac{0 - (\frac{1}{6})(-3)}{6} = \frac{1}{12},$$

$$A_2 = \frac{1 - (\frac{1}{6})(1) - (\frac{1}{12})(-3)}{6} = \frac{13}{72}$$

$$m = 3, \quad f_0 = 0 - \tfrac{1}{6}(0) - \tfrac{1}{12}(1) - \tfrac{13}{72}(-3) = \tfrac{11}{24}$$
$$f_1 = 0 - \tfrac{1}{6}(0) - \tfrac{1}{12}(0) - \tfrac{13}{72}(1) = -\tfrac{13}{72}$$

III. *Repeated Linear Factors*

$$\frac{N(x)}{(x-a)^mG(x)} = \frac{A_0}{(x-a)^m} + \frac{A_1}{(x-a)^{m-1}} + \cdots + \frac{A_{m-1}}{(x-a)} + \frac{F(x)}{G(x)}$$

Change to form $\dfrac{N'(y)}{y^mG'(y)}$ by substitution of $x = y + a$. Resolve into partial fractions in terms of y as described in Section II. Then express in terms of x by substitution $y = x - a$.

Example: $\dfrac{x-3}{(x-2)^2(x^2+x+1)}$. Let $x - 2 = y$, $x = y + 2$

$$\frac{(y+2)-3}{y^2[(y+2)^2+(y+2)+1]} = \frac{y-1}{y^2(y^2+5y+7)}$$

$$= \frac{A_0}{y^2} + \frac{A_1}{y} + \frac{f_1y+f_0}{y^2+5y+7}$$

$$A_0 = -\tfrac{1}{7} \qquad A_1 = \frac{1 - (-\frac{1}{7})(5)}{7} = \frac{12}{49}$$

$(m = 2)$

$$f_0 = 0 - (-\tfrac{1}{7})(1) - (\tfrac{12}{49})(5) = -\tfrac{53}{49}$$
$$f_1 = 0 - (-\tfrac{1}{7})(0) - (\tfrac{12}{49})(1) = -\tfrac{12}{49}$$

$$\therefore \frac{y-1}{y^2(y^2+5y+7)} = \frac{-\frac{1}{7}}{y^2} + \frac{\frac{12}{49}}{y} + \frac{-\frac{12}{49}y - \frac{53}{49}}{y^2+5y+7}$$

Let $y = x - 2$, then

$$\frac{x-3}{(x-2)^2(x^2+x+1)} = \frac{-\frac{1}{7}}{(x-2)^2} + \frac{\frac{12}{35}}{(x-2)}$$

$$+ \frac{-\frac{12}{49}(x-2) - \frac{53}{49}}{x^2+x+1} = -\frac{1}{7(x-2)^2} + \frac{12}{35(x-2)}$$

$$+ \frac{-12x-29}{49(x^2+x+1)}$$

IV. *Repeated Linear Factors*

Alternative method of determining coefficients:

$$\frac{N(x)}{(x-a)^m G(x)} = \frac{A_0}{(x-a)^m} + \cdots + \frac{A_k}{(x-a)^{m-k}} + \cdots + \frac{A_{m-1}}{x-a} + \frac{F(x)}{G(x)}$$

$$A_k = \frac{1}{k!}\left\{D_x{}^k\left[\frac{N(x)}{G(x)}\right]\right\} x = a$$

Where $D_x{}^k$ is the differentiating operator, and the derivative of zero order is defined as:

$$D_x{}^0 u = u.$$

V. *Factors of Higher Degree*

Factors of higher degree have the corresponding numerators indicated.

$$\frac{N(x)}{(x^2+h_1x+h_0)G(x)} = \frac{a_1x+a_0}{x^2+h_1x+h_0} + \frac{F(x)}{G(x)}$$

$$\frac{N(x)}{(x^2+h_1x+h_0)^2G(x)} = \frac{a_1x+a_0}{(x^2+h_1x+h_0)^2} + \frac{b_1x+b_0}{(x^2+h_1x+h_0)} + \frac{F(x)}{G(x)}$$

$$\frac{N(x)}{(x^3+h_2x^2+h_1x+h_0)G(x)} = \frac{a_2x^2+a_1x+a_0}{x^3+h_2x^2+h_1x+h_0} + \frac{F(x)}{G(x)}$$

etc.

Problems of this type are determined first by solving for the coefficients due to linear factors as shown above, and then determining the remaining coefficients by the general methods given below.

VI. *General Methods for Evaluating Coefficients*

1. $$\frac{N(x)}{D(x)} = \frac{N(x)}{G(x)H(x)L(x)} = \frac{A(x)}{G(x)} + \frac{B(x)}{H(x)} + \frac{C(x)}{L(x)} + \cdots$$

Multiply both sides of equation by $D(x)$ to clear fractions. Then collect terms, equate like powers of x, and solve the resulting simultaneous equations for the unknown coefficients.

2. Clear fractions as above. Then let x assume certain convenient values ($x = 1, 0, -1, \ldots$). Solve the resulting equations for the unknown coefficients.

3. $$\frac{N(x)}{G(x)H(x)} = \frac{A(x)}{G(x)} + \frac{B(x)}{H(x)}$$

Then $$\frac{N(x)}{G(x)H(x)} - \frac{A(x)}{G(x)} = \frac{B(x)}{H(x)}$$

If $A(x)$ can be determined, such as by Method I, then $B(x)$ can be found as above.

APPROXIMATIONS

If a and b are small quantities, the following relations are approximately true,—

$$(1\pm a)^m = 1 \pm ma,$$

$$(1\pm a)^m (1\pm b)^n = 1 \pm ma \pm nb.$$

If n is nearly equal to m,

$$\sqrt{mn} = \frac{n+m}{2}, \text{ approximately.}$$

If θ is a very small angle expressed in radians,—

$$\frac{\sin\theta}{\theta} = 1 \text{ and } \frac{\tan\theta}{\theta} = 1, \text{ approximately.}$$

SERIES

The expression in parentheses following certain of the series indicates the region of convergence. If not otherwise indicated it is to be understood that the series converges for all finite values of x.

Binomial

$$(x+y)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{3!}x^{(n-3)}y^3 + \cdots \quad (y^2 < x^2)$$

$$(1\pm x)^n = 1 \pm nx + \frac{n(n-1)x^2}{2!} \pm \frac{n(n-1)(n-2)x^3}{3!} + \cdots \text{ etc.} \quad (x^2<1)$$

$$(1\pm x)^{-n} = 1 \mp nx + \frac{n(n+1)x^2}{2!} \mp \frac{n(n+1)(n+2)x^3}{3!} + \cdots \text{ etc.} \quad (x^2<1)$$

$$(1\pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4 \mp x^5 + \cdots \quad (x^2<1)$$

$$(1\pm x)^{-2} = 1 \mp 2x + 3x^2 \mp 4x^3 + 5x^4 \mp 6x^5 + \cdots \quad (x^2<1)$$

Reversion of Series

Let a series be represented by

$$y = a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + \cdots \quad (a_1 \neq 0)$$

to find the coefficients of the series

$$x = A_1y + A_2y^2 + A_3y^3 + A_4y^4 + \cdots$$

$$A_1 = \frac{1}{a_1} \qquad A_2 = -\frac{a_2}{a_1{}^3} \qquad A_3 = \frac{1}{a_1{}^5}(2a_2{}^2 - a_1a_3)$$

$$A_4 = \frac{1}{a_1{}^7}(5a_1a_2a_3 - a_1{}^2a_4 - 5a_2{}^3)$$

$$A_5 = \frac{1}{a_1{}^9}(6a_1{}^2a_2a_4 + 3a_1{}^2a_3{}^2 + 14a_2{}^4 - a_1{}^3a_5 - 21a_1a_2{}^2a_3)$$

$$A_6 = \frac{1}{a_1{}^{11}}(7a_1{}^3a_2a_5 + 7a_1{}^3a_3a_4 + 84a_1a_2{}^3a_3 - a_1{}^4a_6 - 28a_1{}^3a_2{}^2a_4 - 28a_1{}^3a_2a_3{}^2 - 42a_2{}^5)$$

$$A_7 = \frac{1}{a_1^{13}}(8a_1^4a_2a_6 + 8a_1^4a_3a_5 + 4a_1^4a_4^2 + 120a_1^2a_2^3a_4 + 180a_1^2a_2^2a_3^2 + 132a_2^6 - a_1^5a_7 - 36a_1^3a_2^2a_5 - 72a_1^3a_2a_3a_4 - 12a_1^3a_3^3 - 330a_1a_2^4a_3)$$

Taylor's Series

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2!}f''(x) + \frac{h^3}{3!}f'''(x) + \cdots$$
$$= f(h) + xf'(h) + \frac{x^2}{2!}f''(h) + \frac{x^3}{3!}f'''(h) + \cdots$$

Maclaurin's Series

$$f(x) = f(o) + xf'(o) + \frac{x^2}{2!}f''(o) + \frac{x^3}{3!}f'''(o) + \cdots$$

Exponential

$$e = 1 + \frac{1}{1} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \cdots$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots \quad \text{(all real values of } x\text{)}$$

$$a^x = 1 + x\log_e a + \frac{(x\log a)^2}{2!} + \frac{(x\log a)^3}{3!} + \cdots$$

Logarithmic

$$\log x = \frac{x-1}{x} + \frac{1}{2}\left(\frac{x-1}{x}\right)^2 + \frac{1}{3}\left(\frac{x-1}{x}\right)^3 + \cdots \quad (x > \tfrac{1}{2})$$

$$\log x = (x-1) - \tfrac{1}{2}(x-1)^2 + \tfrac{1}{3}(x-1)^3 - \cdots \quad (2 > x > 0)$$

$$\log x = 2\left[\frac{x-1}{x+1} + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \frac{1}{5}\left(\frac{x-1}{x+1}\right)^5 + \cdots\right] \quad (x > 0)$$

$$\log_e(1+x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 + \cdots \quad (-1 < x < 1)$$

$$\log_e(n+1) - \log_e(n-1) = 2\left[\frac{1}{n} + \frac{1}{3n^3} + \frac{1}{5n^5} + \cdots\right]$$

$$\log_e(a+x) = \log_e a + 2\left[\frac{x}{2a+x} + \frac{1}{3}\left(\frac{x}{2a+x}\right)^3 + \frac{1}{5}\left(\frac{x}{2a+x}\right)^5 + \cdots\right] \quad (a > 0,\ -a < x < +\infty)$$

Trigonometric

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots \quad \text{(all real values of } x\text{)}$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots \quad \text{(all real values of } x\text{)}$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \cdots \quad \left(x^2 < \frac{\pi^2}{4}\right)$$

$$\sin^{-1} x = x + \frac{x^3}{6} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{x^5}{5} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{5}{6}\cdot\frac{x^7}{7} + \cdots \quad (x^2 < 1)$$

$$\tan^{-1} x = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + \cdots \quad (x^2 < 1)$$
$$= \frac{\pi}{2} - \frac{1}{x} + \frac{1}{3x^3} - \frac{1}{5x^5} + \cdots \quad (x^2 > 1)$$

$$\log_e \sin x = \log_e x - \frac{x^2}{6} - \frac{x^4}{180} - \frac{x^6}{2835} - \cdots \quad (x^2 < \pi^2)$$

$$\log_e \cos x = -\frac{x^2}{2} - \frac{x^4}{12} - \frac{x^6}{45} - \frac{17x^8}{2520} - \cdots \quad \left(x^2 < \frac{\pi^2}{4}\right)$$

$$\log_e \tan x = \log_e x + \frac{x^2}{3} + \frac{7x^4}{90} + \frac{62x^6}{2835} + \cdots \quad \left(x^2 < \frac{\pi^2}{4}\right)$$

$$e^{\sin x} = 1 + x + \frac{x^2}{2!} - \frac{3x^4}{4!} - \frac{8x^5}{5!} - \frac{3x^6}{6!} + \frac{56x^7}{7!} + \cdots$$

$$e^{\cos x} = e\left(1 - \frac{x^2}{2!} + \frac{4x^4}{4!} - \frac{31x^6}{6!} + \cdots\right)$$

$$e^{\tan x} = 1 + x + \frac{x^2}{2!} + \frac{3x^3}{3!} + \frac{9x^4}{4!} + \frac{37x^5}{5!} + \cdots \quad \left(x^2 < \frac{\pi^2}{4}\right)$$

FOURIER SERIES

$$f(x) = \frac{a_0}{2} + a_1\cos\frac{2\pi x}{T} + a_2\cos\frac{4\pi x}{T} + \cdots + a_m\cos\frac{2\pi mx}{T} + \cdots + b_1\sin\frac{2\pi x}{T} + b_2\sin\frac{4\pi x}{T} + \cdots + b_n\sin\frac{2\pi nx}{T} + \cdots$$

where

$$a_0 = \frac{2}{T}\int_c^{c+T} f(x)dx, \quad a_m = \frac{2}{T}\int_c^{c+T} f(x)\cos\frac{2\pi mx}{T}dx, \quad b_n = \frac{2}{T}\int_c^{c+T} f(x)\sin\frac{2\pi nx}{T}dx,$$

and $f(x+T) = f(x)$, with c and T constants.

ALGEBRA (Continued)

(See index for Cosine and Sine Transforms)

Auxiliary Formulas for Fourier Series

$$1 = \frac{4}{\pi}\left[\sin\frac{\pi x}{k} + \frac{1}{3}\sin\frac{3\pi x}{k} + \frac{1}{5}\sin\frac{5\pi x}{k} + \cdots\right] \quad [0 < x < k]$$

$$x = \frac{2k}{\pi}\left[\sin\frac{\pi x}{k} - \frac{1}{2}\sin\frac{2\pi x}{k} + \frac{1}{3}\sin\frac{3\pi x}{k} - \cdots\right] \quad [-k < x < k]$$

$$x = \frac{k}{2} - \frac{4k}{\pi^2}\left[\cos\frac{\pi x}{k} + \frac{1}{3^2}\cos\frac{3\pi x}{k} + \frac{1}{5^2}\cos\frac{5\pi x}{k} + \cdot\right] \quad [0 < x < k]$$

$$x^2 = \frac{2k^2}{\pi^3}\left[\left(\frac{\pi^2}{1} - \frac{4}{1}\right)\sin\frac{\pi x}{k} - \frac{\pi^2}{2}\sin\frac{2\pi x}{k} + \left(\frac{\pi^2}{3} - \frac{4}{3^3}\right)\sin\frac{3\pi x}{k} - \frac{\pi^2}{4}\sin\frac{4\pi x}{k} + \left(\frac{\pi^2}{5} - \frac{4}{5^3}\right)\sin\frac{5\pi x}{k} + \cdots\right] \quad [0 < x < k]$$

$$x^2 = \frac{k^2}{3} - \frac{4k^2}{\pi^2}\left[\cos\frac{\pi x}{k} - \frac{1}{2^2}\cos\frac{2\pi x}{k} + \frac{1}{3^2}\cos\frac{3\pi x}{k} - \frac{1}{4^2}\cos\frac{4\pi x}{k} + \cdots\right] \quad [-k < x < k]$$

$$1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots = \frac{\pi}{4}$$

$$1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \cdots = \frac{\pi^2}{6} = B_1\pi^2$$

$$1 - \frac{1}{2^2} + \frac{1}{3^2} - \frac{1}{4^2} + \cdots = \frac{\pi^2}{12} = \frac{B_1\pi^2}{2}$$

$$1 + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \cdots = \frac{\pi^2}{8} = \frac{3B_1\pi^2}{4}$$

$$\frac{1}{2^2} + \frac{1}{4^2} + \frac{1}{6^2} + \frac{1}{8^2} + \cdots = \frac{\pi^2}{24} = \frac{B_2\pi^4}{90}$$

In the above B_1, B_2 . . . represent the Bernoulli Numbers.

Bernoulli Numbers and Euler Numbers

The sequence of numbers E_1, E_2, E_3, . . . obtained from

$$E_n = \frac{(2n)!}{(2n-2)!2!}E_{n-1} - \frac{(2n)!}{(2n-4)!4!}E_{n-2} + \cdots + (-1)^{n-1}$$

are called Euler Numbers. Thus $E_1 = 1$, $E_2 = 5$, $E_3 = 61$, $E_4 = 1385$, $E_5 = 50{,}521$, ...

In the above $0! = 1$ and $E_0 = 1$ by definition.

The sequence of numbers B_1, B_2, B_3, B_4, . . . obtained from

$$B_n = \frac{2n}{2^{2n}(2^{2n}-1)}\left[\frac{(2n-1)!}{(2n-2)!1!}E_{n-1} - \frac{(2n-1)!}{(2n-4)!3!}E_{n-2} + \cdots + (-1)^{n-1}\right]$$

are called Bernoulli numbers. Thus

$B_1 = \frac{1}{6}$, $B_2 = \frac{1}{30}$, $B_3 = \frac{1}{42}$, $B_4 = \frac{1}{30}$, $B_5 = \frac{5}{66}$, . . .

$$B_n = \frac{(2n)!}{\pi^{2n}2^{2n-1}}\left[1 + \frac{1}{2^{2n}} + \frac{1}{3^{2n}} + \frac{1}{4^{2n}} + \cdots\right]$$

$$B_n = \frac{(2n)!}{\pi^{2n}(2^{2n-1}-1)}\left[1 - \frac{1}{2^{2n}} + \frac{1}{3^{2n}} - \frac{1}{4^{2n}} + \cdots\right]$$

$$B_n = \frac{2(2n)!}{\pi^{2n}(2^{2n}-1)}\left[1 + \frac{1}{3^{2n}} + \frac{1}{5^{2n}} + \frac{1}{7^{2n}} + \cdots\right]$$

$$E_n = \frac{2^{2n+2}(2n)!}{\pi^{2n+1}}\left[1 - \frac{1}{3^{2n+1}} + \frac{1}{5^{2n+1}} + \frac{1}{7^{2n+1}} + \cdots\right]$$

VECTOR ANALYSIS

Definitions

Any quantity which is completely determined by its magnitude is called a *scalar*. Examples of such are mass, density, temperature, etc. Any quantity which is completely determined by its magnitude and direction is called a *vector*. Examples of such are velocity, acceleration, force, etc. A vector quantity is represented by a directed line segment, the length of which represents the magnitude of the vector. A vector quantity is usually represented by a bold-faced letter such as $\mathbf{V}$. Two vectors $\mathbf{V}_1$ and $\mathbf{V}_2$ are equal to one another if they have equal magnitudes and are acting in the same directions. A negative vector, written as $-\mathbf{V}$, is one which acts in the opposite direction to $\mathbf{V}$, but is of equal magnitude to it. If we represent the magnitude of $\mathbf{V}$ by v, we write $|\mathbf{V}| = v$. A vector parallel to $\mathbf{V}$, but equal to the reciprocal of its magnitude is written as $\mathbf{V}^{-1}$ or as $\frac{1}{\mathbf{V}}$.

The unit vector $\frac{\mathbf{V}}{|\mathbf{V}|}$ $(\mathbf{V} \neq 0)$ is the one which has the same direction as $\mathbf{V}$, but has a magnitude of 1. (Sometimes represented as $\mathbf{V}^0$.)

Vector Algebra

The vector sum of $\mathbf{V}_1$ and $\mathbf{V}_2$ is represented by $\mathbf{V}_1 + \mathbf{V}_2$. The vector sum of $\mathbf{V}_1$ and $-\mathbf{V}_2$, or the difference of the vector $\mathbf{V}_2$ from $\mathbf{V}_1$ is represented by $\mathbf{V}_1 - \mathbf{V}_2$.

If r is a scalar, then $r\mathbf{V} = \mathbf{V}r$, and represents a vector r times the magnitude of $\mathbf{V}$, in the same direction as $\mathbf{V}$ if r is positive, and in the opposite direction if r is negative. If r and s are scalars, $\mathbf{V}_1$, $\mathbf{V}_2$, $\mathbf{V}_3$, vectors, then the following rules of scalars and vectors hold:

$$\mathbf{V}_1 + \mathbf{V}_2 = \mathbf{V}_2 + \mathbf{V}_1$$
$$(r+s)\mathbf{V}_1 = r\mathbf{V}_1 + s\mathbf{V}_1; \qquad r(\mathbf{V}_1 + \mathbf{V}_2) = r\mathbf{V}_1 + r\mathbf{V}_2$$
$$\mathbf{V}_1 + (\mathbf{V}_2 + \mathbf{V}_3) = (\mathbf{V}_1 + \mathbf{V}_2) + \mathbf{V}_3 = \mathbf{V}_1 + \mathbf{V}_2 + \mathbf{V}_3$$

If $\mathbf{V}_1$ is a vector in space, and a_1, b_1, c_1, the respective magnitudes of the projections of the vector along the coordinate Ox, Oy, Oz axes, then

$\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$, where $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ are respectively the unit vectors along Ox, Oy, and Oz. Its magnitude is

$$|\mathbf{V}_1| = \sqrt{a_1^2 + b_1^2 + c_1^2},$$

and its direction cosines satisfy the proportion

$$a_1 : b_1 : c_1 = \cos\alpha : \cos\beta : \cos\gamma.$$

Thus, if $\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$ and $\mathbf{V}_2 = a_2\mathbf{i} + b_2\mathbf{j} + c_2\mathbf{k}$,
Then $\mathbf{V}_1 + \mathbf{V}_2 = (a_1 + a_2)\mathbf{i} + (b_1 + b_2)\mathbf{j} + (c_1 + c_2)\mathbf{k}$

ALGEBRA (Continued)

The Scalar, Dot, or Inner Product of Two Vectors $\mathbf{V}_1$ and $\mathbf{V}_2$

This product is represented as $\mathbf{V}_1 \ \mathbf{V}_2$ and is defined to be equal to $|\mathbf{V}_1|\ |\mathbf{V}_2| \cos\theta$, where θ is the angle from $\mathbf{V}_1$ to $\mathbf{V}_2$, i.e.,

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = |\mathbf{V}_1|\ |\mathbf{V}_2| \cos\theta$$

The following rules apply for this product:

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = a_1a_2 + b_1b_2 + c_1c_2 = \mathbf{V}_2 \cdot \mathbf{V}_1$$

It should be noted that scalar multiplication is commutative.

If $\mathbf{V}_1 = \mathbf{V}_2$, then $\mathbf{V}_1 \cdot \mathbf{V}_2 = |\mathbf{V}_1|^2$
$(\mathbf{V}_1 + \mathbf{V}_2) \cdot \mathbf{V}_3 = \mathbf{V}_1 \cdot \mathbf{V}_3 + \mathbf{V}_2 \cdot \mathbf{V}_3$
$\mathbf{V}_1 \cdot (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \cdot \mathbf{V}_2 + \mathbf{V}_1 \cdot \mathbf{V}_3$
$\mathbf{i} \cdot \mathbf{i} = \mathbf{j} \cdot \mathbf{j} = \mathbf{k} \cdot \mathbf{k} = 1; \qquad \mathbf{i} \cdot \mathbf{j} = \mathbf{j} \cdot \mathbf{k} = \mathbf{k} \cdot \mathbf{i} = 0$

The Vector or Cross Product of Vectors $\mathbf{V}_1$ and $\mathbf{V}_2$

This product is represented as $\mathbf{V}_1 \times \mathbf{V}_2$ and is defined to be equal to $|\mathbf{V}_1|\ |\mathbf{V}_2|$ (sin θ)$\mathbf{I}$, where θ is the angle from $\mathbf{V}_1$ to $\mathbf{V}_2$ and $\mathbf{I}$ is a unit vector perpendicular to the plane of $\mathbf{V}_1$ and $\mathbf{V}_2$ and so directed that a right-handed screw driven in the direction of $\mathbf{I}$ would carry $\mathbf{V}_1$ into $\mathbf{V}_2$,, i.e.,

$$\mathbf{V}_1 \times \mathbf{V}_2 = |\mathbf{V}_1|\ |\mathbf{V}_2| \ (\sin\theta)\mathbf{I}$$

The following rules apply for vector products:

$\mathbf{V}_1 \times \mathbf{V}_2 = -\mathbf{V}_2 \times \mathbf{V}_1$
$\mathbf{V}_1 \times (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \times \mathbf{V}_2 + \mathbf{V}_1 \times \mathbf{V}_3$
$(\mathbf{V}_1 + \mathbf{V}_2) \times \mathbf{V}_3 = \mathbf{V}_1 \times \mathbf{V}_3 + \mathbf{V}_2 \times \mathbf{V}_3$
$\mathbf{V}_1 \times (\mathbf{V}_2 \times \mathbf{V}_3) = \mathbf{V}_2(\mathbf{V}_3 \cdot \mathbf{V}_1) - \mathbf{V}_3(\mathbf{V}_1 \cdot \mathbf{V}_2)$
$\mathbf{i} \times \mathbf{i} = \mathbf{j} \times \mathbf{j} = \mathbf{k} \times \mathbf{k} = 0$ (zero vector)
$= 0$
$\mathbf{i} \times \mathbf{j} = \mathbf{k}, \qquad \mathbf{j} \times \mathbf{k} = \mathbf{i}, \qquad \mathbf{k} \times \mathbf{i} = \mathbf{j}$
If $\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}, \qquad \mathbf{V}_2 = a_2\mathbf{i} + b_2\mathbf{j} + c_2\mathbf{k},$
$\mathbf{V}_3 = a_3\mathbf{i} + b_3\mathbf{j} + c_3\mathbf{k},$

then

$$\mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \end{vmatrix} = (b_1c_2 - b_2c_1)\mathbf{i} + (c_1a_2 - c_2a_1)\mathbf{j} + (a_1b_2 - a_2b_1)\mathbf{k}$$

It should be noted that, since $\mathbf{V}_1 \times \mathbf{V}_2 = -\mathbf{V}_2 \times \mathbf{V}_1$, the vector product is not commutative.

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 \times \mathbf{V}_3) = (\mathbf{V}_1 \times \mathbf{V}_2) \cdot \mathbf{V}_3 = \mathbf{V}_2 \cdot (\mathbf{V}_3 \times \mathbf{V}_1)$$

$$= (\mathbf{V}_1\mathbf{V}_2\mathbf{V}_3) = \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}$$

which is equal to the volume of a parallelepiped whose three determining edges are $\mathbf{V}_1$, $\mathbf{V}_2$, $\mathbf{V}_3$.

Differentiation of Vectors

If $\mathbf{V}_1 = a_1\mathbf{i} + b_1\mathbf{j} + c_1\mathbf{k}$, and $\mathbf{V}_2 = a_2\mathbf{i} + b_2\mathbf{j} + c_2\mathbf{k}$, and if $\mathbf{V}_1$ and $\mathbf{V}_2$ are functions of the scalar t, then

$$\frac{d}{dt}(\mathbf{V}_1 + \mathbf{V}_2 + \cdots) = \frac{d\mathbf{V}_1}{dt} + \frac{d\mathbf{V}_2}{dt} + \cdots,$$

where $\dfrac{d\mathbf{V}_1}{dt} = \dfrac{da_1}{dt}\mathbf{i} + \dfrac{db_1}{dt}\mathbf{j} + \dfrac{dc_1}{dt}\mathbf{k}$, etc.

$$\frac{d}{dt}(\mathbf{V}_1 \cdot \mathbf{V}_2) = \frac{d\mathbf{V}_1}{dt} \cdot \mathbf{V}_2 + \mathbf{V}_1 \cdot \frac{d\mathbf{V}_2}{dt}$$

$$\frac{d}{dt}(\mathbf{V}_1 \times \mathbf{V}_2) = \frac{d\mathbf{V}_1}{dt} \times \mathbf{V}_2 + \mathbf{V}_1 \times \frac{d\mathbf{V}_2}{dt}$$

Differential Operators—Rectangular Coordinates

By definition

$$\nabla \equiv \text{del} \equiv \mathbf{i}\frac{\partial}{\partial x} + \mathbf{j}\frac{\partial}{\partial y} + \mathbf{k}\frac{\partial}{\partial z}$$

$$\nabla^2 \equiv \text{Laplacian} \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$$

If S is a scalar function, then

$$\nabla S \equiv \text{grad } S \equiv \frac{\partial S}{\partial x}\mathbf{i} + \frac{\partial S}{\partial y}\mathbf{j} + \frac{\partial S}{\partial z}\mathbf{k}$$

The *distributive* law holds for finding a gradient. Thus if S and T are scalar functions

$$\nabla(S + T) = \nabla S + \nabla T$$

The *associative* law becomes the rule for differentiating a product:

$$\nabla(ST) = S\nabla T + T\nabla S$$

If $\mathbf{V}$ is a vector function with the magnitudes of the components parallel to the three coordinate axes V_x, V_y, V_z, then

$$\nabla \cdot \mathbf{V} \equiv \text{div } \mathbf{V} \equiv \frac{\partial V_x}{\partial x} + \frac{\partial V_y}{\partial y} + \frac{\partial V_z}{\partial z}$$

ALGEBRA (Continued)
VECTOR ANALYSIS (Continued)

VECTOR ANALYSIS (Continued)

The divergence obeys the distributive law. Thus, if $\mathbf{V}$ and $\mathbf{U}$ are vector functions, then

$$\nabla \cdot (\mathbf{V} + \mathbf{U}) = \nabla \cdot \mathbf{V} + \nabla \cdot \mathbf{U}$$

$$\nabla \times \mathbf{V} \equiv \operatorname{curl} \mathbf{V} \equiv \operatorname{rot} \mathbf{V} \equiv \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ V_x & V_y & V_z \end{vmatrix}$$

The operator ∇ can be used more than once. The number of possibilities where ∇ is used twice are

$$\begin{aligned} \nabla \cdot (\nabla\theta) &\equiv \operatorname{div} \operatorname{grad} \theta \\ \nabla \times (\nabla\theta) &\equiv \operatorname{curl} \operatorname{grad} \theta \\ \nabla(\nabla \cdot \mathbf{V}) &\equiv \operatorname{grad} \operatorname{div} \mathbf{V} \\ \nabla \cdot (\nabla \times \mathbf{V}) &\equiv \operatorname{div} \operatorname{curl} \mathbf{V} \\ \nabla \times (\nabla \times \mathbf{V}) &\equiv \operatorname{curl} \operatorname{curl} \mathbf{V} \end{aligned}$$

Thus: $\operatorname{div} \operatorname{grad} S \equiv \nabla \cdot (\nabla S) \equiv \text{Laplacian } S \equiv \nabla^2 S$

$$\equiv \frac{\partial^2 S}{\partial x^2} + \frac{\partial^2 S}{\partial y^2} + \frac{\partial^2 S}{\partial z^2}$$

$\operatorname{curl} \operatorname{grad} S \equiv 0$; $\quad \operatorname{curl} \operatorname{curl} \mathbf{V} \equiv \operatorname{grad} \operatorname{div} \mathbf{V} - \nabla^2 \mathbf{V}$; $\quad \operatorname{div} \operatorname{curl} \mathbf{V} \equiv 0$

Green's Theorem

Let $\mathbf{F}$ be a vector function and v a volume bounded by a surface s, then

$$\iiint_{(v)} \operatorname{div} \mathbf{F}\, dv = \iiint_{(v)} \nabla \cdot \mathbf{F}\, dv = \iint_{(s)} \mathbf{F} \cdot ds,$$

where the integrations are to be carried out over the volume v and the surface s.

Stokes Theorem

Let $\mathbf{F}$ be a vector function and s a surface bounded by a simple closed curve c, then

$$\int_{(c)} \mathbf{F} \cdot d\mathbf{1} = \iint_{(s)} (\nabla \times \mathbf{F}) \cdot ds = \iint_{(s)} \operatorname{curl} \mathbf{F} \cdot ds,$$

where the integrations are to be carried out over the curve c and the surface s. It should be noted that

$$d\mathbf{1} = dx\,\mathbf{i} + dy\,\mathbf{j} + dz\,\mathbf{k}$$

The theorem implies that the line integral of $\mathbf{F}$ over the contour c equals the surface integral of $\nabla \times \mathbf{F}$ over a surface s which is bounded by c.

MISCELLANEOUS

The Sum (Σ, = Sigma) and Product (Π, = Pi) Notations

Σ denotes the **sum,** and Π, the **product** of all quantities of a given collection. In particular,

$\sum_{i=m}^{m+n} x_i$ means $x_m + x_{m+1} + \ldots + x_{m+n}$, $(n+1$ terms in all),

$\prod_{i=m}^{m+n} x_i$ means $x_m x_{m+1} \ldots x_{m+n}$, $(n+1$ factors in all).

For indicated **range,** R, (such as $m \leq i \leq m+n$), one may write $\sum_R x_i$, $\prod_R x_i$, respectively. Where the range is clear from the context one writes Σx_i, Πx_i, or even Σx, Πx, respectively. For c a constant and for x_i and y_i with common range (say of n elements),

$$\Sigma c x_i = c\Sigma x_i,\ \Sigma(x_i + y_i) = \Sigma x_i + \Sigma y_i,\ \Sigma(x_i + c) = nc + \Sigma x_i$$

Special Numerical Relations

(i) For range, $i = 1, 2, \ldots, n$, with $x_i = i$.
$\Sigma x_i = n(n+1)/2$, $\Sigma(2x_i - 1) = n^2$,
$\Sigma x_i^2 = n(n+1)(2n+1)/6$.
$\Sigma x_i^3 = (\Sigma x_i)^2$, $\Sigma x_i^4 = (\Sigma x_i^2)[6(\Sigma x_i) - 1]/5$.
$\Pi(c + 1 - x_i) = c^{(n)}$, $\Pi x_i = n^{(n)} = n!$ (**"factorial n"**).
Hence $n! = n \cdot (n-1)!$ $\quad 0!$ is defined to be 1.
Stirling's formula (used for n large),

$$\sqrt{2n\pi}(n/e)^n < n! < \sqrt{2n\pi}(n/e)^n\left(1 + \frac{1}{12n-1}\right),$$

$(\pi = 3.14159 \ldots,\ e = 2.71828 \ldots)$.

$n!/(n-m)!$ gives the number of **permutations of n distinct things taken m at a time.**

(ii) For range, $i = -\left(\frac{n-1}{2}\right), -\left(\frac{n-1}{2}\right) + 1, \ldots, \left(\frac{n-1}{2}\right) - 1, \left(\frac{n-1}{2}\right)$, with

$x_i = i$ (whether n is odd or even),

$$\sum x_i = \sum x_i^3 = 0,\ \sum x_i^2 = \frac{n(n^2-1)}{12},\ \sum x_i^4 = \frac{3n^2-7}{20}\sum x_i^2.$$

Special Numerical Relations

(Continued)

(iii) **The Binomial Coefficients,** $\binom{n}{m}$.

$\binom{n}{m} = n!/[(n-m)!m!]$, for integers m, n, $0 \leq m \leq n$. $\binom{n}{0} = \binom{n}{n} = 1$.

$(x+c)^n = \sum_r \binom{n}{r} x^{n-r}c^r$, $(0 \leq r \leq n)$, the **binomial expansion.** $\binom{n}{m}$ gives also the number of **combinations of n distinct things taken m at a time.**

$\binom{n}{m} + \binom{n}{m+1} = \binom{n+1}{m+1}$, **recursion relation** for binomial coefficients.

$$\binom{n}{n-m} = \binom{n}{m}, \quad \sum_r (-1)^r \binom{n}{r} = 0, \quad \sum_r \binom{n}{r}^2 = \binom{2n}{n}, \quad \sum_{s=m}^{n} \binom{s}{m} = \binom{n+1}{m+1}.$$

Table of Binomial Coefficients

n	$\binom{n}{0}$	$\binom{n}{1}$	$\binom{n}{2}$	$\binom{n}{3}$	$\binom{n}{4}$	$\binom{n}{5}$	$\binom{n}{6}$	$\binom{n}{7}$	$\binom{n}{8}$	$\binom{n}{9}$	$\binom{n}{10}$

20	1	20	190	1140	4845	15504	38760	77520	125970	167960	184756

NOTE: $\binom{n}{m} = \frac{n(n-1)(n-2)\ldots(n-m+1)}{m(m-1)(m-2)\ldots 3.2.1}$; $\binom{n}{0} = 1$; $\binom{n}{1} = n$.

For coefficients missing from the above table, use the relation

$\binom{n}{m} = \binom{n}{n-m}$, e.g. $\binom{20}{11} = \binom{20}{9} = 167960$.

Finite Differences

For equi-spaced arguments x_i, and associated y_i, the successive **advancing y-differences** are, $\Delta^0 y_i = y_i$, $\Delta y_i = y_{i+1} - y_i$, $\Delta^2 y_i = \Delta y_{i+1} - \Delta y_i = y_{i+2} - 2y_{i+1} + y_i, \ldots,$ $\Delta^m y_i = \Delta^{m-1} y_{i+1} - \Delta^{m-1} y_i = \sum_r (-1)^r \binom{m}{r} y_{i+m-r}$. With arbitrary origin A and class-interval length, $x_{i+1} - x_i = h$, using $u_i = (x_i - A)/h$, write $y(u_i)$ for y_i. Then if for some fixed m, for the portion of the table considered, the values of $\Delta^{m+1} y_i$ be zero (or approximately, if these be regarded as negligible) **Newton's formula** gives

$$y(u) = \sum \frac{u^{(r)}}{r!}\Delta^r y(0) = y(0) + u\Delta y(0) + \frac{u(u-1)}{1\cdot 2}\Delta^2 y(0) + \cdots + \frac{u(u-1)\ldots(u-m+1)}{m!}\Delta^m y(0).$$

This formula reduces to an identity for $u = u_0, u_1, \ldots, u_n$, $(u_i = i)$, and may be used to interpolate for intermediate values.

Example. Given

x	-4,	-2,	0,	2,	4,	6,	8,	$\ldots$.
y	10,	14,	30,	64,	122,	210,	334,	$\ldots$.

to find a value for y when $x = 10$, and when $x = 1$. Suppose for some reason A has been taken at $x = 2$. The work may be arranged as follows:

u	x	y	Δ	Δ^2	Δ^3	Δ^4
-3	-4	10				
			4			
-2	-2	14		12		
			16		6	
-1	0	30		18		0
			34		6	
0	2	64		24		0
			58		6	
1	4	122		30		0
			88		6	
2	6	210		36		—
			124		—	
3	8	334		—		—
			—		—	
—	—	—		—		—

$$y(u) = 64 + 58u + 30\frac{u(u-1)}{1\cdot 2} + 6\frac{u(u-1)(u-2)}{1\cdot 2\cdot 3}$$
$$= 64 + 58u + 15u(u-1) + u(u-1)(u-2).$$

At $x = 10$, $u = 4$. Substituting $u = 4$, one has $y|_{x=10} = 500$.

At $x = 1$, $u = -\frac{1}{2}$. Substituting $u = -\frac{1}{2}$, one has $y|_{x=1} = 44\frac{1}{8}$.

ALGEBRA (Continued)

Central Measures

Here the range of i is from 1 to n. With each value x_i is associated a weighting factor $f_i \geq 0$ (such as the frequency the probability, the mass, the reliability, or other multiplier).

N, the **total weight**, $= \Sigma f_i$.

$\bar{x}$, the **arithmetic mean**, $= \Sigma f_i x_i / N = \Sigma f_i x_i / \Sigma f_i$.

GM, the **geometric mean** (available when each x_i is positive), $= \sqrt[N]{\Pi x_i^{f_i}}$. $\text{Log } GM = \Sigma f_i \log x_i / N$.

Mo, the **mode**, = value among $(x_1, \ldots, x_n)$ having maximum associated f_i (usually obtained by interpolating after the data are graduated). For unweighted items, x_i, a mode is a value about which the values of x_i cluster most densely.

RMS, the **root-mean-square**, $= \sqrt{\Sigma f_i x_i^2 / N}$.

Md, the **median** (see below). For unweighted items, the median is the value, equaled or exceeded by exactly half of the values x_i in the given list. In case of a central pair, the median is usually taken as the arithmetic mean of this pair.

Mm, the **mid-mean** (see below). For unweighted items, the mid-mean is the arithmetic mean of the half-list obtained upon dropping out the highest quarter and lowest quarter of the items.

Cum $f|_X$, the value of "cumulative f" at X, $= \sum_{x_i < X} f_i$ (interpolation being used for X if necessary).

The M-Tiles

For **ungrouped data**, X is called the **rth m-tile** (or **rth m-tile mark**) $(r = 0, 1, \ldots, m)$ if simultaneously, $\sum_{x_i < X} f_i / N \leq r/m$, and $\sum_{x_i > X} f_i / N \leq (m - r)/m$. In particular the zeroth m-tile **is min**, the minimal value among the list $(x_1, \ldots, x_n)$, **and the** m**th** m-tile is **max**, the maximal value among the list.

For **grouped data**, the rth m-tile mark, X, is such that

$$\text{Cum } f|_X = Nr/m, \ (r = 0, 1, 2, \ldots, m).$$
$$\text{Cum } f|_{\min} = 0, \qquad \text{Cum } f|_{\max} = N.$$

In particular, certain intermediate $(0 < r < m)$ m-tile marks are named as follows:

m	$r = 1$	2	3	
2	Md (median)			
3	T_1 (lower tertile)	T_2 (upper tertile)		
4	Q_1 (lower quartile)	Md	Q_3 (upper quartile)	
10	D_1 (first decile)	D_2	D_3	etc
100	PC_1 (first percentile)	PC_2	PC_3	etc

The term "**r**th **m-tile**" $(r = 1, \ldots, m)$ is also used to denote the class interval extending from the $(r-1)$st to rth m-tile mark as defined above.

Mm, the **mid-mean**, $=$

$$2 \sum_{Q_1 \leq x_i \leq Q_3} f_i x_i / N = \sum_{Q_1 \leq x_i \leq Q_3} f_i x_i \Big/ \sum_{Q_1 \leq x_i \leq Q_3} f_i.$$

When each x_i is positive, and not all are equal, one always has $0 < \min < GM < \bar{x} < RMS < \max$.

For moderately-skewed distributions, one has approximately $Mo - \bar{x} = 3(Md - \bar{x})$, or $3Md = Mo + 2\bar{x}$.

Measures of Dispersion and Skewness

Here A is an arbitrary reference value, usually a convenient integral measure near $\bar{x}$.

ν_k, k**th moment about** A, $= \Sigma f_i (x_i - A)^k / N$, $(k = 0, 1, \ldots)$.

$\nu_0 = 1$, $\nu_1 = \bar{x} - A$. ν_2 as function of A is minimum for $A = \bar{x}$.

μ_k, k**th moment about** $\bar{x}$, $= \Sigma f_i (x_i - \bar{x})^k / N$, $(k = 0, 1, \ldots)$.

$$\mu_0 = 1,$$
$$\mu_1 = 0,$$
$$\mu_2 = \nu_2 - \nu_1^2 \ (\mu_2 = \text{variance}),$$
$$\mu_3 = \nu_3 - 3\nu_1\nu_2 + 2\nu_1^3,$$
$$\mu_4 = \nu_4 - 4\nu_1\nu_3 + 6\nu_1^2\nu_2 - 3\nu_1^4.$$
$$\beta_1 = \mu_3^2/\mu_2^3, \ \beta_2 = \mu_4/\mu_2^2.$$

σ, **standard deviation**, $= \sqrt{\mu_2}$.

$\alpha_3/2$, **momental skewness**; $\alpha_3 = \sqrt{\beta_1} = \mu_3/\sigma^3$.

$(\alpha_4 - 3)/2$, **kurtosis**; $\alpha_4 = \beta_2$.

MD, **mean deviation** (from the mean), $= \Sigma f_i |x_i - \bar{x}| / N$

$$= 2\left[\bar{x} \sum_{x_i < \bar{x}} f_i - \sum_{x_i < \bar{x}} f_i x_i\right] / N.$$ (This latter form is convenient for computation.)

s, **quartile deviation**, $= |Q_3 - Q_1|/2$.

$P.E.$, **probable error**, $= 0.6745\sigma$.

V, **coefficient of variation**, $= 100\sigma/\bar{x}\ \%$.

Pearson's measure of skewness $= (\bar{x} - Mo)/\sigma$. (Usually approximately $\alpha_3/2$.)

Bowley's measure of skewness $= (Q_3 - 2Md + Q_1)/(2s)$. (Bowley's measure of skewness lies between -1 and $+1$.)

The Class Interval

$$\Delta x_i = x_{i+1} - x_i.$$

For equi-spaced arguments, $\Delta x_i = h$, the **length of the class interval**, x_i is the mid-value or class mark. The interval from $x_i - (h/2)$ to $x_i + (h/2)$ is the **class interval** with these as given **initial** and **terminal end values.**

$$u_i = (x_i - A)/h.$$
$$\bar{u} = \Sigma f_i u_i / N, \ \bar{x} = h\bar{u} + A.$$
$$(\mu_k)_x = h^k(\mu_k)_u, \ (k = 0, 1, \ldots).$$
$$\sigma_u^2 = [\Sigma f_i u_i^2/N] - \bar{u}^2, \ \sigma_x = h\sigma_u.$$
$$(\beta_1)_x = (\beta_1)_u, \ (\beta_2)_x = (\beta_2)_u.$$

Sheppard's corrections (to correct approximately for the error due to treating all elements in a given class interval of length h as though concentrated at the class mark).

For μ_0, μ_1, μ_2, no corrections.

In x-units,

corrected $(\mu_2)_x$ = uncorrected $(\mu_2)_x - h^2/12$,

corrected $(\mu_4)_x$ = uncorrected $(\mu_4)_x - h^2$ uncorrected $(\mu_2)_x/2 + 7h^4/240$.

In u-units, replace h by 1 in the formulae given above.

Least Squares

The **normal equations** for finding coefficients, $a_0, a_1, \ldots, a_m$, in fitting a curve of the form $y = a_0 + a_1x + \ldots + a_mx^m$ to data $(X_i, Y_i), i = 1, \ldots, n, (n > m)$, are $m + 1$ in number as follows:

$$\Sigma Y_i = a_0 n + a_1 \Sigma X_i + a_2 \Sigma X_i^2 + \ldots + a_m \Sigma X_i^m,$$
$$\Sigma X_i Y_i = a_0 \Sigma X_i + a_1 \Sigma X_i^2 + a_2 \Sigma X_i^3 + \ldots + a_m \Sigma X_i^{m+1},$$
$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots$$
$$\Sigma X_i^m Y_i = a_0 \Sigma X_i^m + a_1 \Sigma X_i^{m+1} + a_2 \Sigma X_i^{m+2} + \ldots + a_m \Sigma X_i^{2m}.$$

Deviation from fitted curve,

$$d_i = Y_i - (a_0 + a_1X_i + \ldots + a_mX_i^m).$$

$$\Sigma d_i^2 = \Sigma Y_i^2 - (a_0 \Sigma Y_i + a_1 \Sigma X_i Y_i + \ldots + a_m \Sigma X_i^m Y_i).$$

For $z = ab^x$, use $y = \log z$, $a_0 = \log a$, $a_1 = \log b$.

For $z = at^p$, use $y = \log z$, $a_0 = \log a$, $a_1 = p$, $x = \log t$.

S_y, **standard error of estimate**, = root-mean-square of the y-deviations about a fitted curve $= \sqrt{\Sigma d_i^2/n}$.

Simple Correlation

Product Moment Method

Given n equi-spaced measurements $X_i, i = 1, 2, \ldots, n$, with $h = X_{i+1} - X_i$, $x_i = X_i - \bar{X}$; and m equi-spaced measurements $Y_j, j = 1, 2, \ldots, m$, with $k = Y_{j+1} - Y_j$, $y_j = Y_j - \bar{Y}$; and a weight (frequency, probability, etc.) e_{ij} (≥ 0), associated with (X_i, Y_j). Here e_{ij} is an entry in the table.

$$f_i = \sum_j e_{ij}, \ g_j = \sum_i e_{ij}.$$

$$N = \sum_{ij} e_{ij} = \sum_i f_i = \sum_j g_j. \quad \text{(Check)}$$

$$\bar{x} = \sum_{ij} e_{ij}X_i/N = \sum_i f_iX_i/N; \ \bar{y} = \sum_{ij} e_{ij}Y_j/N = \sum_j g_jY_j/N.$$

Let A and B be arbitrary reference values, usually convenient integral measures near $\bar{X}$ and $\bar{Y}$, respectively.

$$u_i = (X_i - A)/h, \ v_j = (Y_j - B)/k;$$

$$\bar{u} = \Sigma f_i u_i/N, \ \bar{X} = h\bar{u} + A, \ \bar{v} = \Sigma g_j v_j/N, \ \bar{Y} = k\bar{v} + B.$$

$$\left.\begin{aligned} \sigma_u^2 &= (\mu_2)_u = (\Sigma f_i u_i^2/N) - \bar{u}^2, \ \sigma_x = h\sigma_u. \\ \sigma_v^2 &= (\mu_2)_v = (\Sigma g_j v_j^2)/N - \bar{v}^2, \ \sigma_y = k\sigma_v. \end{aligned}\right\} \text{Apply Sheppard's corrections.}$$

$$U_j = \sum_i e_{ij}u_i, \ V_i = \sum_j e_{ij}v_j, \ P = \sum u_iV_i = \sum v_jU_j, \quad \text{(Check)}$$

$$p_{uv} = \sum_{ij} e_{ij}(u_i - \bar{u})(v_j - \bar{v})/N$$
$$= (P/N) - \bar{u}\bar{v}.$$

$$p_{xy} = hkp_{uv}.$$

$r = p_{uv}/(\sigma_u\sigma_v) = p_{xy}/(\sigma_x\sigma_y)$ (**product-moment**) **coefficient of correlation.** In every case $-1 \leq r \leq 1$.

$Y - \bar{Y} = r\frac{\sigma_y}{\sigma_x}(X - \bar{X})$, or $y = r\frac{\sigma_y}{\sigma_x}x$, **regression line of y on x.**

$X - \bar{X} = r\frac{\sigma_x}{\sigma_y}(Y - \bar{Y})$, or $x = r\frac{\sigma_x}{\sigma_y}y$, **regression line of x on y.**

Example of Computation for Product-Moment Coefficient of Correlation

v_j \ u_i	y_j \ x_i	−3	−2	−1	0	1	2	g_j	g_jv_j	$g_jv_j^2$	U_j $\left(-\sum_i e_{ij}u_i\right)$	v_jU_j
		12	16	20	24	28	32					
2	21			1	5	7	1	14	28	56	8	16
1	18		1	3	7	5	2	18	18	18	4	4
0	15		2	3	4	1		10	0	0		0
−1	12		3	1	1			5	−5	5	−7	7
−2	9	2	1					3	−6	12	−8	16
f_i		2	7	8	17	13	3	50	35	91		43
f_iu_i		−6	−14	−8	0	13	6	−9				
$f_iu_i^2$		18	28	8	0	13	12	79				
$V_i\left(-\sum_j e_{ij}v_j\right)$		−4	−4	4		19	4					
u_iV_i		12	8	−4	0	19	8	43				

$A = 24, B = 15,$
$h = 4, k = 3,$
$N = \Sigma f_i = \Sigma g_j = 50,$
$\Sigma f_iu_i = -9, \Sigma g_jv_j = 35,$
$\Sigma f_iu_i^2 = 79, \Sigma g_jv_j^2 = 91,$
$P = \Sigma u_iV_i = \Sigma v_jU_j = 43.$

$\bar{u} = -\frac{9}{50} = -.18 \quad \bar{v} = \frac{35}{50} = .70$

$\sigma_u^2 = (\frac{79}{50}) - (-.18)^2 - .083 = 1.46, \quad \sigma_u = 1.21$

$\sigma_v^2 = (\frac{91}{50}) - (.70)^2 - .083 = 1.247, \quad \sigma_v = 1.117$

$p_{uv} = (\frac{43}{50}) - (-.18)(.70) = +0.986$

$r = +0.986/(1.21 \times 1.117) = +.730.$ Ans. $r = +.730$

Rank Difference Method

Given n corresponding pairs of measured items (X_i, Y_i), $(i = 1, \ldots, n)$. Let (u_i, v_i) be the corresponding rank numbers. Here $u_i = 1$ for the largest X_i, 2 for the next largest X_i, etc., and similarly $v_i = 1$ for the largest Y_i, 2 for the next largest Y_i, etc. $\rho = 1 - \dfrac{6\Sigma(u_i - v_i)^2}{n(n^2-1)}$, **(rank difference) coefficient of correlation.** In every case $-1 \leq \rho \leq 1$. Check: $\Sigma(u_i - v_i) = 0$.

Example of Computation for Rank-Difference Coefficient of Correlation

X_i	Y_i	u_i	v_i	$u_i - v_i$	$(u_i - v_i)^2$	
76	52	3	1	+2	4	Check: $\Sigma(u_i - v_i) = 0$.
66	34	8	9	−1	1	
63	32	10	10	0	0	
74	45	4	4	0	0	$\rho = 1 - \dfrac{6 \times 62}{10(10^2-1)}$
79	50	1	2	−1	1	
69	37	7	7	0	0	$= +0.63$
77	35	2	8	−6	36	
65	42	9	5	+4	16	Ans. $\rho = +.63$
71	40	6	6	0	0	
73	48	5	3	+2	4	
$N = 10$				0	62	

Probability

If among $a + b$ equi-probable and mutually exclusive events, a are regarded as favorable and b unfavorable, then for a single trial

p, probability of favorable outcome, $= \dfrac{a}{a+b}$,

q, probability of unfavorable outcome, $= 1 - p = \dfrac{b}{a+b}$.

The successive terms in the binomial expansion $(p+q)^n = \sum_r \binom{n}{r} p^{n-r} q^r$ give the respective probabilities that in n trials, the event will be favorable exactly $n - r$ times, $r = 0, \ldots, n$.

The mean number of favorable events is np, of unfavorable, nq; the standard deviation is $\sigma = \sqrt{npq}$, $\alpha_3 = (p-q)/\sigma$ (the positive direction being that of increasing unfavorability).

Normal curve (x measured in σ-units from the mean, and with area = 1):

$$y = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} = 0.3989 e^{-x^2/2}.$$

MD (mean deviation from the mean) $= \sigma\sqrt{2/\pi} = 0.7979\sigma$

s (quartile deviation from the mean) $= 0.6745\sigma = 0.845\ MD$.

Percentage areas, under normal curve, for successive class intervals measured from the mean:

Multiples of σ: 34 %, 14 %, 2 %.

Multiples of s: 25 %, 16 %, 7 %, 2 %.

Normal surface (x measured in σ_x-units y in σ_y-units from their means),

$$z = \frac{1}{2\pi\sqrt{1-r^2}} e^{-(x^2 - 2rxy + y^2)/[2(1-r^2)]}.$$

***Goodness of Fit.** For a universe of objects falling into n mutually exclusive classes with class marks, $x_i (i = 1, 2, \ldots, n)$, let p_i be the probability for the ith class. Given a sample of N items, with f_i items in the ith class ($\Sigma f_i = N$), the probability that a random sample of N items gives no better fit, expressed in terms of n and χ^2 ("Chi square"), $= \Sigma(f_i - Np_i)^2/(Np_i)$, is given by a table, portions of which are as follows:

Probability that a Random Sample Gives no Better Fit

n \ χ^2	1	2	3	4	6	8	10	15	20
3	.607	.368	.223	.135	.050	.018	.007	.001	.000

Plane Figures Bounded by Straight Lines

The **area of a triangle** whose base is b and altitude h

$$= \frac{hb}{2}.$$

The area of a **triangle** with angles A, B, and C and sides opposite a, b, and c, respectively

$$= \tfrac{1}{2}ab \sin C.$$

or
$$= \sqrt{s(s-a)(s-b)(s-c)},$$

where $s = \tfrac{1}{2}(a+b+c)$.

A **rectangle** with sides a and b has an area $= ab$.

The area of a **parallelogram** with side b and the perpendicular distance to the parallel side h

$$= bh.$$

The area of a **parallelogram** with sides a and b and the included angle θ

$$= ab \sin \theta.$$

The area of a **rhombus** with diagonals c and d,

$$= \tfrac{1}{2}cd.$$

The area of a **trapezoid** whose parallel sides are a and b and altitude h

$$= \tfrac{1}{2}(a+b)h.$$

The area of any **quadrilateral** with diagonals a and b and the angle between them θ

$$= \tfrac{1}{2}ab \sin \theta.$$

The area of a **regular polygon** with n sides, each of length l,

$$= \tfrac{1}{4}nl^2 \cot \frac{180^\circ}{n}.$$

For a regular polygon of n sides, each side of length l, the radius of the **inscribed circle**,

$$= \frac{l}{2}\cot \frac{180^\circ}{n}.$$

The radius of the circumscribed circle,

$$= \frac{l}{2}\operatorname{cosec} \frac{180^\circ}{n}.$$

Area, Radius of Inscribed and Circumscribed Circles for Regular Polygons

l = length of one side.

Name.	Number of sides.	Area.	Radius of inscribed circle.	Radius of circumscribed circle.
Triangle, equilateral	3	$0.43301l^2$	$0.28867l$	$0.57735l$
Square	4	$1.00000l^2$	$0.50000l$	$0.70710l$
Pentagon	5	$1.72048l^2$	$0.68819l$	$0.85065l$
Hexagon	6	$2.59808l^2$	$0.86602l$	$1.0000l$
Heptagon	7	$3.63391l^2$	$1.0383l$	$1.1523l$

Radius of circle inscribed in any triangle, whose sides are a, b, and c, where $s = \tfrac{1}{2}(a+b+c)$ is given by r

$$= \frac{\sqrt{s(s-a)(s-b)(s-c)}}{s}.$$

The radius of the **circumscribed** circle is given by R

$$= \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}.$$

The **perimeter of a polygon inscribed in a circle** of radius where n is the number of sides,

$$= 2nr \sin \frac{\pi}{n}. \qquad (\pi \text{ radians} = 180^\circ)$$

The area of the **inscribed** polygon,

$$= \tfrac{1}{2}nr^2 \sin \frac{2\pi}{n}.$$

The perimeter of a polygon circumscribed about a circle of radius r, number of sides n

$$= 2nr \tan \frac{\pi}{n}.$$

The area of the **circumscribed** polygon

$$= nr^2 \tan \frac{\pi}{n}.$$

Plane Figures Bounded by Curved Lines

The **circumference of a circle** whose radius is r and diameter $d(d = 2r)$

$$= 2\pi r = \pi d. \qquad (\pi = 3.14159)$$

The **area of a circle**

$$= \pi r^2 = \tfrac{1}{4}\pi d^2 = .7854 d^2.$$

The **length of an arc** of a circle for an arc of θ degrees

$$= \frac{\pi r \theta}{180}.$$

NOTE.—In this and following similar formulæ r denotes the radius of the circle, (OC, Fig. 1).

For an arc of θ radians the length s

$$= r\theta.$$

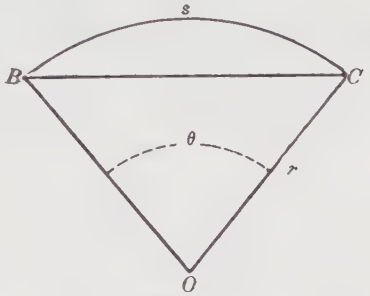

FIG. 1.

The **length of a chord** subtending an angle θ.

$$= 2r \sin \tfrac{1}{2}\theta.$$

The **area of a sector** where θ is the angle between the radii in degrees

$$= \frac{\pi r^2 \theta}{360}.$$

If s is the length of the arc, the area of the sector

$$= \frac{sr}{2}.$$

The **area of a segment** where θ is the angle between the two radii in degrees

$$= \frac{\pi r^2 \theta}{360} - \frac{r^2 \sin \theta}{2} \qquad \left[\begin{array}{l}\theta^\circ = 180^\circ - [2 \sin^{-1}(x/r)] \\ x = \perp \text{ dist. center to chord}\end{array}\right]$$

If θ is in radians the area $= \tfrac{1}{2}r^2(\theta - \sin \theta)$.

The **area of the segment of a circle**

$$= \frac{\pi r^2}{2} - \left[x\sqrt{r^2 - x^2} + r^2 \operatorname{Sin}^{-1}\left(\frac{x}{r}\right) \right]$$

where r is the radius of the circle and x the perpendicular distance of the chord from the center. The principal angle must be used in this formula.

The **area of the ring** between two circles of radius r_1 and r_2, one of which encloses the other,

$$= \pi(r_1 + r_2)(r_1 - r_2).$$

The two circles are not necessarily concentric.

Area of the sector of an annulus. (Fig. 2.)—If angle $GOH = \theta$ and the lines GO and $JO = r_1$ and r_2 respectively, the area $GHIJ = \tfrac{1}{2}\theta(r_1 + r_2)(r_1 - r_2)$.

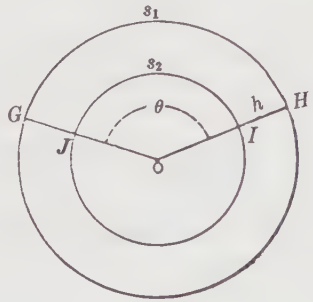

FIG. 2.

If s_1 = the length of the arc GH and s_2 = the arc JI and $h = HI = r_1 - r_2$, the area $GHIJ = \tfrac{1}{2}h(s_1 + s_2)$.

The **circumference of an ellipse** whose semiaxes are a and b

$$= 2\pi\sqrt{\frac{a^2+b^2}{2}} \text{ (approx.)} = 4aE \text{ exactly.}$$

See tables of elliptic integrals for E, using $k = \frac{\sqrt{a^2 - b^2}}{a}$

The **area of an ellipse** $= \pi ab$.

The length of the **arc of a parabola,** as arc SPQ in Fig. 3, where $x = PR$, and $y = QR$

$$\sqrt{4x^2 + y^2} + \frac{y^2}{2x} \log_e \frac{2x + \sqrt{4x^2 + y^2}}{y}$$

The **area of the section of the parabola** $PQRS$, $= \tfrac{4}{3}xy$.

Solids Bounded by Planes

The **lateral area of a regular prism** = perimeter of a right section × the length.

The **volume of a regular prism** = area of base × the altitude.

The **lateral area of a regular pyramid,** slant height l, length of one side of base a, and a number of sides n,

$$= \tfrac{1}{2}nal.$$

The **volume of a pyramid** = $\frac{1}{3}$ area of base × altitude.

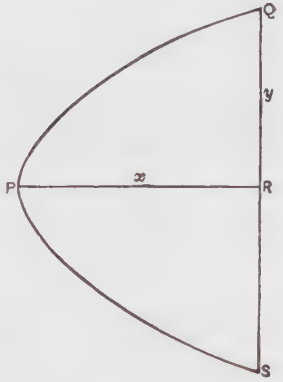

FIG. 3.

Surface and Volume of Regular Polyhedra

Surface and volume of regular polyhedra in terms of the length of one edge l.

Name.	Nature of surface.	Surface.	Volume.
Tetrahedron...	4 equilateral triangles	$1.73205l^2$	$0.11785l^3$
Hexahedron or cube.....	6 squares.....	$6.00000l^2$	$1.00000l^3$
Octahedron....	8 equilateral triangles	$3.46410l^2$	$0.47140l^3$
Dodecahedron .	12 pentagons.....	$20.64573l^2$	$7.66312l^3$
Icosahedron...	20 equilateral triangles	$8.66025l^2$	$2.18170l^3$

Solids Bounded by Curved Surfaces

The **surface of a sphere** of radius r and diameter $d(=2r)$

$$= 4\pi r^2 = \pi d^2 = 12.57r^2.$$

The **volume of a sphere**

$$= \tfrac{4}{3}\pi r^3 = \tfrac{1}{6}\pi d^3 = 4.189r^3.$$

The **area of a lune** on the surface of a sphere of radius r, included between two great circles whose inclination is θ radians.

$$= 2r^2\theta.$$

The **area of a spherical triangle** whose angles are A, B, and C (radians) on a sphere of radius r

$$= (A + B + C - \pi)r^2.$$

The **area of a spherical polygon** of n sides where θ is the sum of its angles in radians

$$= [\theta - (n-2)\pi]r^2.$$

The area of the curved surface of a **spherical segment** of height h, radius of sphere r

$$= 2\pi rh.$$

The **volume of a spherical segment,** data as above

$$= \tfrac{1}{3}\pi h^2(3r - h).$$

If a = radius of the base of the segment, the volume

$$= \tfrac{1}{6}\pi h(h^2 + 3a^2).$$

The **curved surface of a right cylinder where** r = the radius of the base and h, the altitude,

$$= 2\pi rh.$$

The **volume of a cylinder,** data as above,

$$= \pi r^2 h.$$

The **curved surface of a right cone** whose altitude is h and radius of base r

$$= \pi r\sqrt{r^2 + h^2}.$$

The **volume of a cone,** data as above,

$$= \frac{\pi}{3}r^2h = 1.047\,r^2h.$$

The **curved surface of the frustum of a right cone,** radius of base r_1 of top r_2 and altitude h,

$$= \pi(r_1 + r_2)\sqrt{h^2 + (r_1 - r_2)^2}.$$

The **volume of the frustum of a cone,** data as above,

$$= \pi\frac{h}{3}(r_1^2 + r_1r_2 + r_2^2).$$

The **oblate spheroid** is formed by the rotation of an ellipse about its minor axis. If a and b are the major and minor semi-axes respectively, and ϵ the eccentricity, the surface

$$= 2\pi a^2 + \pi\frac{b^2}{\epsilon}\log_e\frac{1+\epsilon}{1-\epsilon},$$

and volume $= \frac{4}{3}\pi a^2 b$.

The prolate spheroid is formed by the rotation of an ellipse about its major axis ($2a$), data as above.

Surface $= 2\pi b^2 + 2\pi \frac{ab}{\epsilon} \sin^{-1}\epsilon,$

volume $= \frac{4}{3}\pi ab^2.$

SIMPSON'S RULE FOR IRREGULAR AREAS

Divide the area into an even number ($2m$) of panels by means of $2m+1$ parallel lines, drawn at constant distance h apart; and denote the lengths of the intercepted segments by $y_0, y_1 \ldots, y_{2m-1}, y_{2m}$. The first and last of these may be zero. The area will then be

$$A = \tfrac{1}{3}h[(y_0+y_{2m}) + 4(y_1+y_3+\ldots + y_{2m-1}) + 2(y_2+y_4+\ldots+y_{2m-2})]$$

While the formula is exact in many simple cases, ordinarily the formula provides only an approximation, for which the accuracy increases with an increase in the number of divisions. Simpson's Rule may be applied to finding volumes, if the measures $y_0, y_1 \ldots, y_{2m}$ be interpreted as the areas of parallel plane sections at constant distance h apart.

PRISMOIDAL FORMULA

As a special case where m=1, and H, (=2h) is the distance between two limiting parallel planes, one has for the volume of a solid figure,

$$V = \tfrac{1}{6}H(S_0 + 4S_1 + S_2).$$

Here S_0 and S_2 are the cross-sectional areas in these limiting planes (lower and upper bases, respectively), and S_1 is the cross section of the mid-section. The formula is exact for the cone, sphere, ellipsoid, and prismoid.

TRIGONOMETRIC FUNCTIONS IN A RIGHT-ANGLED TRIANGLE

If A, B, and C are the vertices (C the right angle), and a, b, and h the sides opposite respectively,

$$\text{sine } A = \sin A = \frac{a}{h}, \qquad \text{cosine } A = \cos A = \frac{b}{h},$$

$$\text{tangent } A = \tan A = \frac{a}{b}, \quad \text{cotangent } A = \cot A = \operatorname{ctn} A = \frac{b}{a},$$

$$\text{secant } A = \sec A = \frac{h}{b}, \qquad \text{cosecant } A = \csc A = \frac{h}{a}.$$

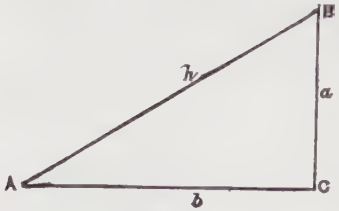

FIG. 4.

exsecant A = exsec A = sec A − 1

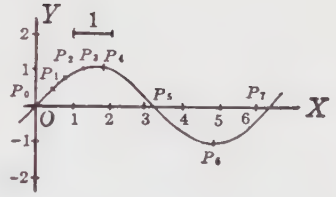
versine A = vers A = 1 − cos A

coversine A = covers A = 1 − sin A

haversine A = hav A = $\frac{1}{2}$ vers A

RELATIONS BETWEEN DEGREE OF ACCURACY OF COMPUTED LENGTHS AND ANGLES

When solving a triangle for any of its parts the following should be observed:



Length to	(requires) Angle to:
2 significant digits	nearest 30′ = 0.5°
3 significant digits	nearest 05′ = 0.083°
4 significant digits	nearest 01′ = 0.0167°
5 significant digits	nearest 0.1′ = 0.00167°

EXPONENTIAL DEFINITIONS OF CIRCULAR FUNCTIONS

$$\sin x = \frac{1}{2i}(e^{ix} - e^{-ix}) \qquad \text{cosec } x = \frac{2i}{e^{ix} - e^{-ix}}$$

$$(i^2 = -1)$$

$$\cos x = \frac{e^{ix} + e^{-ix}}{2} \qquad \sec x = \frac{2}{e^{ix} + e^{-ix}}$$

$$\tan x = \frac{e^{ix} - e^{-ix}}{ie^{ix} + ie^{-ix}} \qquad \cot x = \frac{ie^{ix} + ie^{-ix}}{e^{ix} - e^{-ix}}$$

RELATIONS OF THE FUNCTIONS

$$\sin x = \frac{1}{\text{cosec } x}. \qquad \text{cosec } x = \frac{1}{\sin x}.$$

$$\cos x = \frac{1}{\sec x}. \qquad \sec x = \frac{1}{\cos x}.$$

$$\tan x = \frac{1}{\cot x} = \frac{\sin x}{\cos x}. \qquad \sin^2 x + \cos^2 x = 1.$$

$$\cot x = \frac{1}{\tan x} = \frac{\cos x}{\sin x}. \qquad 1 + \tan^2 x = \sec^2 x.$$

$$1 + \cot^2 x = \text{cosec}^2 x.$$

$$*\sin x = \pm\sqrt{1 - \cos^2 x}. \qquad \cos x = \pm\sqrt{1 - \sin^2 x}.$$

$$\tan x = \pm\sqrt{\sec^2 x - 1}. \qquad \sec x = \pm\sqrt{\tan^2 x + 1}.$$

$$\cot x = \pm\sqrt{\text{cosec}^2 x - 1}. \qquad \text{cosec } x = \pm\sqrt{\cot^2 x + 1}.$$

$$\sin x = \cos(90° - x) = \sin(180° - x).$$

$$\cos x = \sin(90° - x) = -\cos(180° - x).$$

$$\tan x = \cot(90° - x) = -\tan(180° - x).$$

$$\cot x = \tan(90° - x) = -\cot(180° - x).$$

$$\text{cosec } x = \cot\frac{x}{2} - \cot x.$$

* The sign in front of radical depends on quadrant in which x falls.

FUNCTIONS OF SUMS OF ANGLES

$$\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y.$$

$$\cos(x \pm y) = \cos x \cos y \mp \sin x \sin y.$$

$$\tan(x \pm y) = \frac{\tan x \pm \tan y}{1 \mp \tan x \tan y}.$$

FUNCTIONS OF MULTIPLE ANGLES

$$\sin 2x = 2 \sin x \cos x.$$

$$\cos 2x = \cos^2 x - \sin^2 x = 2\cos^2 x - 1 = 1 - 2\sin^2 x.$$

$$\sin 3x = 3 \sin x - 4 \sin^3 x.$$

$$\cos 3x = 4 \cos^3 x - 3 \cos x.$$

$$\sin 4x = 8 \cos^3 x \sin x - 4 \cos x \sin x.$$

$$\cos 4x = 8 \cos^4 x - 8 \cos^2 x + 1.$$

$$\sin 5x = 5 \sin x - 20 \sin^3 x + 16 \sin^5 x.$$

$$\cos 5x = 16 \cos^5 x - 20 \cos^3 x + 5 \cos x.$$

$$\sin 6x = 32 \cos^5 x \sin x - 32 \cos^3 x \sin x + 6 \cos x \sin x.$$

$$\cos 6x = 32 \cos^6 x - 48 \cos^4 x + 18 \cos^2 x - 1.$$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x}$$

$$\cot 2x = \frac{\cot^2 x - 1}{2 \cot x}.$$

FUNCTIONS OF MULTIPLE ANGLES (Continued)

$$\tan 3x = \frac{3\tan x - \tan^3 x}{1 - 3\tan^2 x}.$$

$$*\sin \tfrac{1}{2}x = \pm\sqrt{\frac{1-\cos x}{2}}.$$

$$\cos \tfrac{1}{2}x = \pm\sqrt{\frac{1+\cos x}{2}}.$$

$$\tan \tfrac{1}{2}x = \pm\sqrt{\frac{1-\cos x}{1+\cos x}} = \frac{1-\cos x}{\sin x} = \frac{\sin x}{1+\cos x}.$$

* The sign in front of radical depends on quadrant in which $\frac{x}{2}$ falls.

MISCELLANEOUS RELATIONS

$$\sin x \pm \sin y = 2\sin \tfrac{1}{2}(x \pm y)\cdot\cos \tfrac{1}{2}(x \mp y).$$

$$\cos x + \cos y = 2\cos \tfrac{1}{2}(x+y)\cdot\cos \tfrac{1}{2}(x-y).$$

$$\cos x - \cos y = -2\sin \tfrac{1}{2}(x+y)\cdot\sin \tfrac{1}{2}(x-y).$$

$$\tan x \pm \tan y = \frac{\sin(x \pm y)}{\cos x\cdot\cos y}. \qquad \cot x \pm \cot y = \frac{\pm\sin(x \pm y)}{\sin x\cdot\sin y}.$$

$$\frac{1+\tan x}{1-\tan x} = \tan(45^\circ + x). \qquad \frac{\cot x + 1}{\cot x - 1} = \cot(45^\circ - x)$$

$$\frac{\sin x \pm \sin y}{\cos x + \cos y} = \tan \tfrac{1}{2}(x \pm y).$$

$$\frac{\sin x \pm \sin y}{\cos x - \cos y} = -\cot \tfrac{1}{2}(x \mp y).$$

$$\frac{\sin x + \sin y}{\sin x - \sin y} = \frac{\tan \tfrac{1}{2}(x+y)}{\tan \tfrac{1}{2}(x-y)}.$$

$$\sin^2 x - \sin^2 y = \sin(x+y)\cdot\sin(x-y).$$

$$\cos^2 x - \cos^2 y = -\sin(x+y)\sin(x-y).$$

$$\cos^2 x - \sin^2 y = \cos(x+y)\cos(x-y).$$

INVERSE TRIGONOMETRIC FUNCTIONS

The following table lists each of the six inverse trigonometric functions together with the interval of its principal value:

Function	Interval containing principal value	
	x positive or zero	x negative
$y = \sin^{-1}x$ and $\tan^{-1}x$	$0 \leqq y \leqq \pi/2$	$-\pi/2 \leqq y < 0$
$y = \cos^{-1}x$ and $\cot^{-1}x$	$0 < y \leqq \pi/2$	$\pi/2 < y \leqq \pi$
$y = \sec^{-1}x$ and $\csc^{-1}x$	$0 \leqq y < \pi/2$	$-\pi \leqq y < -\pi/2$

Usually the first letter in "arc" or the name of the inverse trigonometric functions is capitalized if the principal value is desired. Thus

$$\text{Arc}\sin\frac{1}{2} = \text{Sin}^{-1}\frac{1}{2} = \frac{\pi}{6},$$

while $$\text{arc}\sin\frac{1}{2} = \frac{\pi}{6} + 2\pi n \text{ or } \frac{5\pi}{6} + 2\pi n$$

In the calculus both for differentiation and integral formulas, capitalization is not adhered to strictly, but principal values are always understood for inverse trigonometric functions when used unless specifically stated otherwise.

RELATIONS BETWEEN SIDES AND ANGLES OF ANY PLANE TRIANGLE

In a triangle with angles A, B, and C and sides opposite a, b, and c respectively,

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} = \text{diameter of the circumscribed circle.}$$

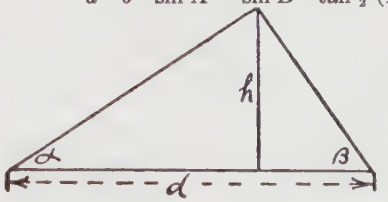
$$a^2 = b^2 + c^2 - 2bc\cos A.$$

$$a = b\cos C + c\cos B.$$

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}.$$

$$\tan\frac{A-B}{2} = \frac{a-b}{a+b}\cot\frac{C}{2}.$$

$$\sin A = \frac{2}{bc}\sqrt{s(s-a)(s-b)(s-c)},$$



where $s = \frac{1}{2}(a+b+c)$ and $r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$.

$$\sin\frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{bc}}.$$

$$\cos\frac{A}{2} = \sqrt{\frac{s(s-a)}{bc}}.$$

$$\tan\frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}} = \frac{r}{s-a}.$$

$$\frac{a+b}{a-b} = \frac{\sin A + \sin B}{\sin A - \sin B} = \frac{\tan \tfrac{1}{2}(A+B)}{\tan \tfrac{1}{2}(A-B)} = \frac{\cot \tfrac{1}{2}C}{\tan \tfrac{1}{2}(A-B)}.$$

$$h = d\frac{\sin\alpha\sin\beta}{\sin(\alpha+\beta)} = \frac{d}{\cot\alpha + \cot\beta}$$

Similarly

$$h = d\frac{\sin\alpha\sin\beta'}{\sin(\beta'-\alpha)} = \frac{d}{\cot\alpha - \cot\beta'}$$

FIG. 5.

RELATIONS IN ANY SPHERICAL TRIANGLE

If A, B and C be the three angles and a, b, and c the opposite sides,

$$\frac{\sin A}{\sin a}=\frac{\sin B}{\sin b}=\frac{\sin C}{\sin c}.$$

$$\cos a=\cos b\cos c+\sin b\sin c\cos A=\frac{\cos b\cos(c\pm\theta)}{\cos\theta}.$$

where $\tan\theta=\tan b\cos A$.

$$\cos A=-\cos B\cos C+\sin B\sin C\cos a.$$

$$\sin\tfrac{1}{2}A=\sqrt{\frac{\sin(s-b)\sin(s-c)}{\sin b\sin c}}.$$

where $s=\tfrac{1}{2}(a+b+c)$.

$$\cos\tfrac{1}{2}A=\sqrt{\frac{\sin s\sin(s-a)}{\sin b\sin c}}.$$

$$\tan\tfrac{1}{2}A=\frac{r}{\sin(s-a)}.$$

where $$r=\sqrt{\frac{\sin(s-a)\sin(s-b)\sin(s-c)}{\sin s}}.$$

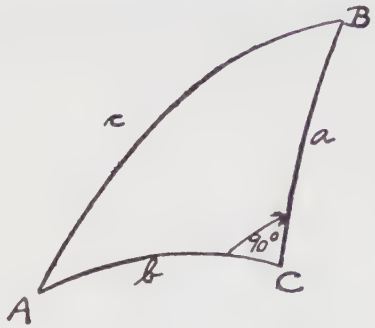
$$\cos\tfrac{1}{2}a=\sqrt{\frac{\cos(S-B)\cos(S-C)}{\sin B\sin C}}.$$

where $S=\tfrac{1}{2}(A+B+C)$.

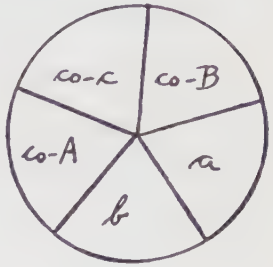
$$\sin\tfrac{1}{2}a=\sqrt{-\frac{\cos S\cos(S-A)}{\sin B\sin C}}.$$

$$\tan\tfrac{1}{2}a=R\cos(S-A)$$

where $$R=\sqrt{\frac{-\cos S}{\cos(S-A)\cos(S-B)\cos(S-C)}}$$



$$\frac{\tan\frac{a+b}{2}}{\tan\frac{c}{2}}=\frac{\cos\frac{A-B}{2}}{\cos\frac{A+B}{2}},\quad\frac{\tan\frac{A+B}{2}}{\cot\frac{C}{2}}=\frac{\cos\frac{a-b}{2}}{\cos\frac{a+b}{2}}.$$



$$\frac{\tan\frac{a-b}{2}}{\tan\frac{c}{2}}=\frac{\sin\frac{A-B}{2}}{\sin\frac{A+B}{2}},\quad\frac{\tan\frac{A-B}{2}}{\cot\frac{C}{2}}=\frac{\sin\frac{a-b}{2}}{\sin\frac{a+b}{2}}$$

$$\operatorname{hav}a=\operatorname{hav}(b-c)+\sin b\sin c\operatorname{hav}A$$

$$\operatorname{hav}A=\frac{\sqrt{\operatorname{hav}[a+(b-c)]\operatorname{hav}[a-(b-c)]}}{\sin b\sin c}$$

NAPIER'S RULES FOR RIGHT SPHERICAL TRIANGLES

Take the five parts, *excluding the right angle* and consider them to be in a circular arrangement.

Attach a "Co" to the two angles and the hypotenuse, meaning "Complement of A" etc. Then:

1. The sine of the middle part equals the product of the tangents of the adjacent parts.
2. The sine of the middle part equals the product of the cosines of the opposite parts. The following rules for determining the quadrant of a calculated part apply:
1. A leg and the angle opposite it are always of the same quadrant.
2. If the hypotenuse is less than 90°, the legs are of the same quadrant. If the hypotenuse is greater than 90°, the legs are of opposite quadrants.

The distance between two points x_1, y_1, and x_2, y_2,—rectangular coördinates:

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

For polar coördinates and points r_1, θ_1, and r_2, θ_2:

$$d = \sqrt{r_1^2 + r_2^2 - 2r_1r_2 \cos(\theta_1 - \theta_2)}$$

The area of a triangle whose vertices are x_1, y_1; x_2, y_2, and x_3, y_3:

$$A = \tfrac{1}{2}|x_1y_2 - x_2y_1 + x_2y_3 - x_3y_2 + x_3y_1 - x_1y_3|$$

For polar coördinates and vertices, r_1, θ_1; r_2, θ_2, and r_3, θ_3:

$$A = \tfrac{1}{2}\{r_1r_2 \sin(\theta_2 - \theta_1) + r_2r_3 \sin(\theta_3 - \theta_2) + r_3r_1 \sin(\theta_1 - \theta_3)\}$$

The equation of a straight line where m is the tangent of the angle of inclination and c, the distance of intersection with the Y axis from the origin:

$$y = mx + c$$

If a line of slope m passes through the point x_1, y_1 its equation is:

$$y - y_1 = m(x - x_1)$$

The equation of a line through the points x_1, y_1, and x_2, y_2 is:

$$\frac{y - y_1}{y_2 - y_1} = \frac{x - x_1}{x_2 - x_1}$$

If the intercepts on the X and Y axes are a and b respectively, the equation is:

$$\frac{x}{a} + \frac{y}{b} = 1$$

If the length of the perpendicular from the origin is p and its angle of inclination θ the equation is:

$$x \cos\theta + y \sin\theta = p$$

General equation of the straight line:

$Ax + By + C = 0$, where slope $m = \dfrac{-A}{B}$; x-intercept $a = \dfrac{-C}{A}$; y-intercept $b = \dfrac{-C}{B}$.

The equation of a circle whose center is at a, b, and whose radius is c:

$$(x - a)^2 + (y - b)^2 = c^2$$

If the origin is at the center:

$$x^2 + y^2 = c^2$$

The polar equation of a circle with the origin on the circumference and its center at point c, a:

$$r = 2c \cos(\theta - a).$$

If the origin is not on the circumference, the radius a and the center at l, a, the equation becomes

$$a^2 = r^2 + l^2 - 2rl \cos(\theta - a).$$

The equation of a parabola with the origin at the vertex, where f is the distance from the focus to the vertex:

$$y^2 = 4fx$$

If p is the semi-latus rectum ($=2f$) the equation is:

$$y^2 = 2px$$

The polar equation where the pole is at the focus and p the semi-latus rectum is:

$$r = \frac{p}{1 - \cos\theta}$$

If the pole is at the vertex and p as above:

$$r = \frac{2p \cos\theta}{\sin^2\theta}$$

The equation of the ellipse with the origin at the center and semi-axes a and b:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Polar equation where the pole is at the center:

$$r^2 = \frac{a^2b^2}{a^2 \sin^2\theta + b^2 \cos^2\theta}$$

The equation of the hyperbola with the origin at the center, semi-axes a and b:

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

Polar equation, pole at center:

$$r^2 = \frac{a^2b^2}{a^2 \sin^2\theta - b^2 \cos^2\theta}$$

TRANSFORMATION OF COORDINATES

Rectangular System

(1) Translation only of axes parallel to themselves.
The coordinates of new origin with respect to old axes: $x = h$, $y = k$. Primed letters designate new coordinates.

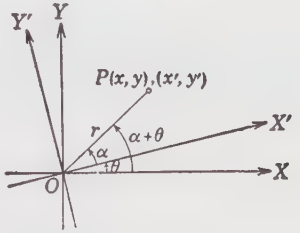
$$x' = x - h \qquad x = x' + h$$
$$y' = y - k \qquad y = y' + k$$

(2) Rotation of axes with fixed origin.

Angle of rotation $= \theta$

$$x' = x\cos\theta + y\sin\theta \qquad x = x'\cos\theta - y'\sin\theta$$
$$y' = y\cos\theta - x\sin\theta \qquad y = y'\cos\theta + x'\sin\theta$$

(3) Origin translated and axes rotated.
Symbols same as above



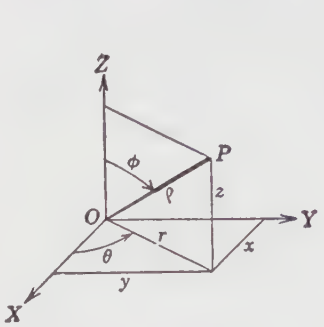
$$x' = (x - h)\cos\theta + (y - k)\sin\theta$$
$$y' = (y - k)\cos\theta - (x - h)\sin\theta$$
$$x = x'\cos\theta - y'\sin\theta + h$$
$$y = y'\cos\theta + x'\sin\theta + k$$

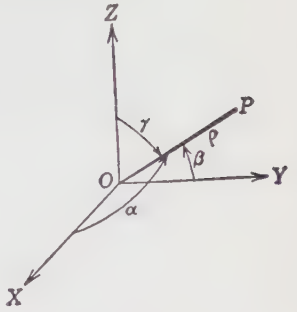
Relation between Rectangular and Polar Coordinates

$$x = r\cos\theta \qquad r = \sqrt{x^2 + y^2} \qquad \sin\theta = \frac{y}{\sqrt{x^2 + y^2}}$$
$$y = r\sin\theta \qquad \theta = \tan^{-1}\frac{y}{x} \qquad \cos\theta = \frac{x}{\sqrt{x^2 + y^2}}$$

Rotation of Polar Axes through Angle θ

$$x' = r\cos\alpha$$
$$y' = r\sin\alpha$$
$$x = r\cos(\alpha + \theta)$$
$$y = r\sin(\alpha + \theta)$$





TRANSFORMATION OF COORDINATES (Continued)

SOLID ANALYTICAL GEOMETRY

Space Coordinates

1. Rectangular System x, y, z.
2. Cylindrical System r, θ, z.
3. Spherical System ρ, θ, ϕ. In certain situations it is desireable to interchange the symbols ϕ for θ and vice versa.
4. Polar Space System $\rho, \alpha, \beta, \gamma$.

Relations of Coordinates of Systems in Terms of x, y, z

Cylindrical	Spherical	Polar Space
$r = \sqrt{x^2 + y^2}$	$\rho = \sqrt{x^2 + y^2 + z^2}$	$\rho = \sqrt{x^2 + y^2 + z^2}$
$\theta = \tan^{-1}\frac{y}{x}$	$\theta = \tan^{-1}\frac{y}{x}$	$\alpha = \cos^{-1}\left(\frac{x}{\sqrt{x^2 + y^2 + z^2}}\right)$
$z = z$	$\phi = \cos^{-1}\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right)$	$\beta = \cos^{-1}\left(\frac{y}{\sqrt{x^2 + y^2 + z^2}}\right)$
		$\gamma = \cos^{-1}\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right)$

Relations of Rectangular Coordinates (x, y, z) in Terms of Cylindrical, Spherical and Polar Space Coordinates

Cylindrical	Spherical	Polar Space
$x = r\cos\theta$ $y = r\sin\theta$ $z = z$	$x = \rho\sin\phi\cos\theta$ $y = \rho\sin\phi\sin\theta$ $z = \rho\cos\phi$	$x = \rho\cos\alpha$ $y = \rho\cos\beta$ $z = \rho\cos\gamma$

TRANSFORMATION OF COORDINATES (Continued)

TRANSFORMATION OF RECTANGULAR SPACE COORDINATES FOR TRANSLATION WITHOUT ROTATION

Coordinates of new origin are (h, k, l) in terms of the old coordinates. New coordinates are (x', y', z')

$$\begin{aligned} x' &= x - h & x &= x' + h \\ y' &= y - k & y &= y' + k \\ z' &= z - l & z &= z' + l \end{aligned}$$

For rotation only about the origin where $\lambda_1, \mu_1, \nu_1; \lambda_2, \mu_2, \nu_2$ and λ_3, μ_3, ν_3 are the direction cosines of the new axes with respect to the old axes. The coordinates of point P are (x, y, z) referred to the original axes and (x', y', z') referred to the new rotated axes.

$$\begin{aligned} x' &= \lambda_1 x + \mu_1 y + \nu_1 z \\ y' &= \lambda_2 x + \mu_2 y + \nu_2 z \\ z' &= \lambda_3 x + \mu_3 y + \nu_3 z \\ x &= \lambda_1 x' + \lambda_2 y' + \lambda_3 z' \\ y &= \mu_1 x' + \mu_2 y' + \mu_3 z' \\ z &= \nu_1 x' + \nu_2 y' + \nu_3 z' \end{aligned}$$

HYPERBOLIC FUNCTIONS

Definitions

An hyperbolic function represents a relation between the coordinates of a given point on the arc of a rectangular hyperbola.

If O is the center, A the vertex, and P any point of the hyperbola APB,

$OM = x$,
$MP = y$,
$OA = a$.

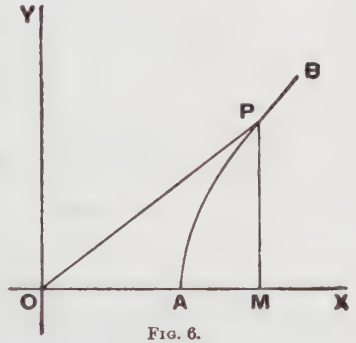


FIG. 6.

The function u may be defined by the following relation,

$$u = \frac{2 \times \text{Area OAP}}{OA^2}$$

The hyperbolic sine of u = $\sinh u = y/a$.
The hyperbolic cosine of u = $\cosh u = x/a$.

Exponential Definitions of Hyperbolic Functions and Their Power Series

$$\sinh u = \frac{e^u - e^{-u}}{2} = \frac{1}{2}(e^u - e^{-u}) = u + \frac{u^3}{3!} + \frac{u^5}{5!} + \cdots$$

$$\cosh u = \frac{e^u + e^{-u}}{2} = \frac{1}{2}(e^u + e^{-u}) = 1 + \frac{u^2}{2!} + \frac{u^4}{4!} + \cdots$$

$$\tanh u = \frac{e^u - e^{-u}}{e^u + e^{-u}} = u - \frac{u^3}{3} + \frac{2u^5}{15} - \frac{17u^7}{315} + \cdots \qquad \left(u^2 < \tfrac{1}{4}\pi^2\right).$$

$$\sinh^{-1} u = u - \frac{1}{2}\cdot\frac{u^3}{3} + \frac{1\cdot 3}{2\cdot 4}\cdot\frac{u^5}{5} - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{u^7}{7} + \cdots \qquad (u^2 < 1).$$

$$\sinh^{-1} u = \log 2u + \frac{1}{2}\cdot\frac{1}{2u^2} - \frac{1\cdot 3}{2\cdot 4}\cdot\frac{1}{4u^4} + \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{1}{6u^6} - \cdots \qquad (u^2 > 1).$$

$$\cosh^{-1} u = \log 2u - \frac{1}{2}\cdot\frac{1}{2u^2} - \frac{1\cdot 3}{2\cdot 4}\cdot\frac{1}{4u^4} - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{1}{6u^6} - \cdots \qquad (u^2 > 1).$$

$$\tanh^{-1} u = u + \frac{u^3}{3} + \frac{u^5}{5} + \frac{u^7}{7} + \cdots \qquad (u^2 < 1).$$

$$\tanh u = \frac{\sinh u}{\cosh u}. \qquad \operatorname{sech} u = \frac{1}{\cosh u}.$$

$$\coth u = \frac{1}{\tanh u}. \qquad \operatorname{csch} u = \frac{1}{\sinh u}.$$

Relations of the Functions

$\sinh x = -\sinh(-x)$. $\quad \operatorname{sech} x = \operatorname{sech}(-x)$.
$\cosh x = \cosh(-x)$. $\quad \operatorname{csch} x = -\operatorname{csch}(-x)$.
$\tanh x = -\tanh(-x)$. $\quad \coth x = -\coth(-x)$.

$$\sinh x = \frac{2\tanh \tfrac{1}{2}x}{1 - \tanh^2 \tfrac{1}{2}x} = \frac{\tanh x}{\sqrt{1 - \tanh^2 x}}.$$

$$\cosh x = \frac{1 + \tanh^2 \tfrac{1}{2}x}{1 - \tanh^2 \tfrac{1}{2}x} = \frac{1}{\sqrt{1 - \tanh^2 x}}.$$

$$\cosh^2 x - \sinh^2 x = 1.$$

$\tanh x = \sqrt{1 - \operatorname{sech}^2 x}$. $\quad \operatorname{sech} x = \sqrt{1 - \tanh^2 x}$.
$\coth x = \sqrt{\operatorname{csch}^2 x + 1}$. $\quad \operatorname{csch} x = \sqrt{\coth^2 x - 1}$.

Relations of the Functions (Continued)

$\sinh(\frac{1}{2}x) = \sqrt{\frac{1}{2}(\cosh x - 1)}$.
$\cosh(\frac{1}{2}x) = \sqrt{\frac{1}{2}(\cosh x + 1)}$.
$\tanh(\frac{1}{2}x) = (\cosh x - 1) \div \sinh x = \sinh x \div (\cosh x + 1)$.
$\sinh(2x) = 2 \sinh x \cosh x$.
$\cosh(2x) = \cosh^2 x + \sinh^2 x = 2\cosh^2 x - 1 = 1 + 2\sinh^2 x$
$\tanh(2x) = 2 \tanh x \div (1 + \tanh^2 x)$.
$\sinh 3x = 3 \sinh x + 4 \sinh^3 x$.
$\cosh 3x = 4 \cosh^3 x - 3 \cosh x$.
$\tanh 3x = (3 \tanh x + \tanh^3 x) \div (1 + 3 \tanh^2 x)$.
$\sinh(x \pm y) = \sinh x \cdot \cosh y \pm \cosh x \cdot \sinh y$.
$\cosh(x \pm y) = \cosh x \cdot \cosh y \pm \sinh x \cdot \sinh y$.
$\tanh(x \pm y) = (\tanh x \pm \tanh y) \div (1 \pm \tanh x \cdot \tanh y)$.
$\sinh x + \sinh y = 2 \sinh \frac{1}{2}(x + y) \cdot \cosh \frac{1}{2}(x - y)$.
$\sinh x - \sinh y = 2 \cosh \frac{1}{2}(x + y) \cdot \sinh \frac{1}{2}(x - y)$.
$\cosh x + \cosh y = 2 \cosh \frac{1}{2}(x + y) \cdot \cosh \frac{1}{2}(x - y)$.
$\cosh x - \cosh y = 2 \sinh \frac{1}{2}(x + y) \cdot \sinh \frac{1}{2}(x - y)$.

$$\sinh x + \cosh x = \frac{1 + \tanh \frac{1}{2}x}{1 - \tanh \frac{1}{2}x}$$

$$\tanh x \pm \tanh y = \frac{\sinh(x \pm y)}{\cosh x \cosh y}.$$

$$\coth x \pm \coth y = \pm \frac{\sinh(x \pm y)}{\sinh x \sinh y}.$$

Inverse Functions

$$\sinh^{-1} x = \log(x + \sqrt{x^2 + 1}) = \int \frac{dx}{\sqrt{x^2 + 1}} = \cosh^{-1}\sqrt{x^2 + 1}$$

$$\cosh^{-1} x = \log(x + \sqrt{x^2 - 1}) = \int \frac{dx}{\sqrt{x^2 - 1}} = \sinh^{-1}\sqrt{x^2 - 1}$$

$$\tanh^{-1} x = \frac{1}{2}\log(1 + x) - \frac{1}{2}\log(1 - x) = \int \frac{dx}{1 - x^2}.$$

$$\coth^{-1} x = \frac{1}{2}\log(1 + x) - \frac{1}{2}\log(x - 1) = \int \frac{dx}{1 - x^2}.$$

$$\operatorname{sech}^{-1} x = \log\left(\frac{1}{x} + \sqrt{\frac{1}{x^2} - 1}\right) = -\int \frac{dx}{x\sqrt{1 - x^2}}.$$

$$\operatorname{csch}^{-1} x = \log\left(\frac{1}{x} + \sqrt{\frac{1}{x^2} + 1}\right) = -\int \frac{dx}{x\sqrt{x^2 + 1}}.$$

Relations to Circular Functions

$\sinh x = -i \sin ix.$	$\sinh ix = i \sin x.$
$\cosh x = \cos ix.$	$\cosh ix = \cos x.$
$\tanh x = -i \tan ix.$	$\tanh ix = i \tan x.$

If $x = \log \tan\left(\frac{\pi}{4} + \frac{\theta}{2}\right) = \log(\sec\theta + \tan\theta)$,

θ = the **gudermannian** of x = gd x.

$\sinh x = \tan \operatorname{gd} x.$	$\tanh x = \sin \operatorname{gd} x.$
$\cosh x = \sec \operatorname{gd} x.$	$\tanh \frac{1}{2} x = \tan \frac{1}{2} \operatorname{gd} x.$

$$\frac{d \operatorname{gd} x}{dx} = \operatorname{sech} x.$$

COMPLETE ELLIPTIC INTEGRALS

$$K = \int_0^{\pi/2} \frac{d\Phi}{\sqrt{1 - k^2 \sin^2 \Phi}} = F\left(k, \frac{\pi}{2}\right)$$

$$E = \int_0^{\pi/2} \sqrt{1 - k^2 \sin^2 \Phi}\, d\Phi = E\left(k, \frac{\pi}{2}\right)$$

See index for other elliptic integral tables.

ATOMIC WEIGHTS

For the sake of completeness all known elements are included in the list. Several of those more recently discovered are represented only by the unstable isotopes. The value in parenthesis in the atomic weight column is, in each case, the mass number of the most stable isotope.**

Name	Symbol	At. No.	International atomic weight		Valence

1. ±0.002
2. ±0.001
3. ±0.001

* Because of natural variations in the relative abundances of the isotopes of sulfur the atomic weight of this element has a range of ±0.003.

** The 1959 atomic weights are based on O = 16.000 whereas those of 1966 are based on the isotope C^{12}.

Numbers in parentheses are mass numbers of most stable isotope of that element.

Table of the Isotopes

compiled by
R. L. Heath

Atomic Energy Division, Phillips Petroleum Company
National Reactor Testing Station
Idaho Falls, Idaho

Data on all the currently known stable and radioactive isotopes are included in this compilation. Major sources of data for this compilation are the following:

1. "Nuclear Data Sheets" of the Nuclear Data Project of the National Academy of Sciences—National Research Council, including all data through May, 1963.
2. D. Strominger, J. M. Hollander, and G. T. Seaborg, "Table of Isotopes," *Revs. Modern Phys.*, **30,** 585 (1958).
3. Where available, current data from original published papers (through May, 1963).
4. Supplementary reference was made to R. L. Heath, "Scintillation Spectrometry Gamma Ray Spectrum Catalogue," U.S. AEC Report IDO-16408 (1958).
5. Values for thermal-neutron cross sections were obtained from BNL-325.

Z (Column 1): This column lists isotopes in order of atomic number.

Isotope (Column 2): Isotopes are listed by chemical designation and atomic number. Isomers are designated by the addition of the superscript *m*.

Atomic mass (Column 4): Values for the atomic masses of the isotopes are listed in this column. Values are given in the physical scale. The atomic-weight system used is based on the arbitrary assignment of the weight of the Carbon 12 isotope to be 12.00000 amu. This system has been recommended by the International Union of Pure and Applied Chemistry and the International Commission of Atomic Weights.

$t_{1/2}$ (Column 5): This column lists the half life of the radioactive isotopes. The notation used for these values is as follows: y = years, d = days, h = hours, m = minutes, s = seconds, ms = milliseconds, and μs = microseconds.

Modes of decay (Column 6): This column lists the observed modes of decay for all radioactive isotopes. In cases of branched decay between two or more modes, the branching ratios in percent are listed as a superscript for each mode of decay. Symbols used are: β^- = negative beta emission, β^+ = positron emission, α = alpha emission, EC = orbital electron capture, IT = isomeric transition from upper to lower isomeric state, n = neutron emission, SF = spontaneous fission.

Decay energy (Column 7): This lists the currently adopted values for the total disintegration energies (Q) in Mev. Where more than one mode of decay exists—separate values will be given if necessary.

Particle energies (Column 8): This column lists end-point energies of beta particles and measured energies of alpha particles in Mev.

Particle intensities (Column 9): In this column intensities of beta groups and alpha particles are listed. Values are either given in percent of decay or as relative intensities where the complete decay scheme is not known. Relative intensities are noted by the symbol†.

Gamma-ray energies (Column 10): Values for gamma-ray energies are listed in Mev. For those nuclides which emit large numbers of gamma rays, only the major gamma rays are listed. In general this includes only gamma rays with relative intensities in the first

decade. For some nuclides which have short-lived daughters, the major gamma rays of the daughters may be included in parenthesis. Delayed gamma rays are noted by the symbol D. The abbreviation Ann. Rad. refers to the 0.511 Mev radiation resulting from the annihilation of positrons.

Gamma-ray intensities (Column 11): This column lists intensities corresponding to gamma rays given in Column 10. Values are given in percent of decays for a given transition, and include a correction for internal conversion. Relative intensities for gamma rays are indicated by the symbol †. In cases where the conversion coefficients are large, both relative gamma intensities and percent decay for the transition are given. The intensity of the conversion electrons for a given gamma ray are sometimes listed in percent of decays with the symbol CE.

Thermal-neutron capture cross sections (Column 12): This column lists cross sections for thermal-neutron capture in barns (10^{-24}cm^2). Where neutron capture for a given nucleus can produce two isomers the separate cross sections are listed as (A + B), where A is the cross section for production of the isomeric level and B is the cross section for production of the ground state. Fission cross sections are listed for some heavy elements together with the symbol σ_f.

TABLE OF THE ISOTOPES

z	Isotope	% nat. abundance	Atomic mass (A)	Lifetime $t_{\frac{1}{2}}$	Modes of decay	Decay energies (Mev)	Particle energies (Mev)	Particle intensities	Gamma energies (Mev)	Gamma intensities	Thermal neutron capture cross-sections (Barns) σ_c

THERMAL NEUTRON CROSS SECTIONS

The table of Thermal Neutron Cross Sections is taken from data published by the Neutron Cross Section Advisory Group of the Atomic Energy Commission, July 1, 1958, by Hughes and Schwartz.

All values given for an element refer to the natural mixture of isotopes, that is, they are atomic cross sections, while those given for specific isotopes are isotopic cross sections. All cross sections, unless marked mb (millibarns) are in barns (10^{-24} cm^2).

The reaction cross sections listed are those for a neutron velocity of 2200 meters per second. The reaction cross sections refer to all cases in which the neutron is not re-emitted, that is, to (n,γ), (n,p), and (n,α) reactions. Practically all the reaction cross sections are for (n,γ) reactions and the few that are not are so marked. The absorption cross sections, σ_{abs}, are the particular reaction cross sections that are measured by observing the reaction itself in which the neutron is absorbed. The activation cross sections, σ_{act}, are those determined from the radioactivity of the product nucleus, usually the result of an (n,γ) reaction, and in a few cases, which are specially marked, by (n,p) or (n,α) reactions. The activation cross sections always refer to particular isotopes and hence are isotopic cross sections; for monoisotopic elements they are atomic cross sections as well. For a few cases in which the 2200 m/s value could not be determined, the cross sections are still included but are marked with an asterisk* indicating "pile neutrons."

The scattering cross sections are usually constant with energy in the thermal region, except for crystal effects, and are hence not quoted for 2200 m/s. The average scattering cross section, $\bar{\sigma}_s$, is that averaged over the Maxwell distribution and will depend on the crystalline form of the sample and even upon the size of the crystal grain, but it is listed here because of utility in certain practical applications.

The Elements

C. R. Hammond

One of the most striking facts about the elements is their unequal distribution and occurrence in nature. Present knowledge of the chemical composition of the universe, obtained from the study of the spectra of stars and nebulae, indicates that hydrogen is by far the most abundant, and may comprise more than 90% of the atoms or about three quarters of the mass of the universe. Helium atoms account for most of the remainder. All of the other elements together probably contribute only slightly more than 1 per cent to the mass.

It is now thought that the chemical composition of the universe is undergoing continuous change. Hydrogen is being converted into helium, and helium is being changed into the heavier elements. As time goes on, the ratio of heavier elements increases relative to hydrogen. The process presumably is not reversible.

Studies of the solar spectrum have led to the identification of 67 elements in the sun's atmosphere; however all elements cannot be identified with the same degree of certainty. Other elements may be present in the sun although they have not yet been detected spectroscopically. The element helium was discovered on the sun before it was found on earth. Some elements, such as scandium, are relatively more plentiful in the sun and the stars than here on earth. No elements are found elsewhere in the universe that cannot now be accounted for on earth; however technetium, an unstable element which probably does not occur naturally on earth, has been identified in the spectra of certain late-type stars. This presents one of the most puzzling current problems of astrophysics.

F. W. Clarke and others have carefully studied the composition of igneous rocks making up the crust of the earth. It has been found that oxygen accounts for about 47% of the crust by weight, while silicon comprises about 28%, and aluminum about 8%. These elements, plus iron, calcium, sodium, potassium, and magnesium, account for about 99% of the earth's crust.

It is surprising that many elements, such as tin, copper, zinc, lead, mercury, silver, platinum, antimony, arsenic, and gold, that are essential to our needs and civilization, are among some of the rarest elements in the earth's crust. These are made available to us only by the processes of concentration in ore bodies. Some of the so-called "rare-earth" elements are now thought to be much more plentiful than originally thought, and are about as abundant as uranium, mercury, lead, or bismuth. The least abundant rare-earth, thulium, is now believed to be more plentiful than silver, gold, or platinum. It is also startling to find in light of recent knowledge that rubidium is the 16th most abundant element and is more plentiful than chlorine, although its compounds are so little known in chemistry and commerce.

Each element, from atomic number 1 to 100 has at least one radioactive isotope. About 1400 different nuclides (the name given to different kinds of nuclei whether they are of the same or different elements) are now recognized. Of these, about 260 are stable forms of natural elements. About 1130 are unstable, 65 of which occur in nature principally among the heaviest elements. More than 300 stable and radioactive isotopes are now produced and distributed by the Oak Ridge National Laboratory to customers licensed by the U. S. Atomic Energy Commission.

The available evidence leads to the conclusion that elements 89 (actinium) through 103 are so chemically similar to the *rare earths* or lanthanide elements (atomic numbers 57–71)

that their electronic structures must also be similar. They have, therefore, been named *actinides,* after the first member of this series. An inner electron shell, consisting of fourteen 5f electrons is filled in progressing across the series. Those elements beyond uranium have been produced artificially on earth by nuclear reactions and synthesis and are known as the *transuranium* elements. The presently known transuranium elements have the following names and symbols: 93, neptunium (Np); 94, plutonium (Pu); 95, americium (Am); 96, curium (Cm); 97, berkelium (Bk); 98, californium (Cf); 99, einsteinium (E); 100, fermium (Fm); 101, mendelevium (Mv); element 102, (unnamed); and element 103, lawrencium (Lw).

Chemically the transuranium elements are very similar, although the observed differences are those expected and anticipated from their unique position in the periodic system as part of a second rare-earth series. All have trivalent ions, which form inorganic complex ions and organic chelates. Also in common are acid-insoluble trifluorides and oxalates, soluble sulfates, nitrates, chlorides, and perchlorates. Neptunium, plutonium, and americium have higher oxidation states in aqueous solution (similar to uranium), but the relative stability of these states to the common trivalent ion becomes progressively less as one proceeds to the higher atomic numbers. This is a direct consequence, indeed an identifying feature, of the actinide role as a second rare-earth type transition series.

One of the most important methods for study and elucidation of chemical behavior of the actinide elements has been ion-exchange chromatography. Adsorption on and elution from ion-exchange columns has made possible the identification and separation of trace quantities of all of the actinides and in particular the transuranium elements. The behavior of each actinide and transuranium element in this respect is very similar to its analogue rare-earth element. This has made it possible to detect as little as one or two atoms when this small a number has been made in some of the transmutation experiments.

At present, eleven transuranium elements have been created and discovered, with a total of about one hundred isotopes. All these new elements are unstable and, therefore, radioactive. The half-life of the various isotopes decreases, in general, with increasing atomic number, which means that as heavier and heavier elements are created, they exist for shorter and shorter periods, making their production, separation, and identification progressively more difficult.

It may still be possible to synthesize, separate, and identify a half-dozen or so more of the transuranium elements, but barring unknown experimental breakthroughs or unknown regions of stability, the end should come somewhere in the region of element 110. The elements up to and including einsteinium, element 99, have isotopes sufficiently long-lived to be isolated in macroscopic quantities, but this does not seem to be true beyond einsteinium. Unfortunately for the prospect of producing ever-higher elements, the longest-lived isotopes that can be made beyond elements 104 and 105 will probably not exist long enough for conventional chemical identification.

ACTINIUM (Gr. *aktis, aktinos,* beam or ray), Ac; at. wt. 227.02 (calc.) at. no. 89; m.p. 1050°C, b.p. 3200°C, ±300°C (est.); sp. g. 10.07 (calc.). Discovered by Andre Debierne in 1899 and independently by F. Giesel in 1902. Occurs naturally in association with uranium minerals. Actinium-227, a decay product of uranium-235, is a beta emitter with a 22-yr. half-life. Its principal decay products are thorium-227 (18.6-day half life), radium-223 (11.2-day half-life), and a number of short-lived products including radon, bismuth, polonium and lead isotopes. In equilibrium with its decay products, it is a powerful source of alpha rays. Actinium has been isolated, and commercial production of the element has been reported. Purified actinium comes into equilibrium with its decay products at the end of 185 days, and then decays according to its 22-yr. half-life. It is about 150 times as active as radium, making it of value in the production of neutrons.

ALUMINUM (L. *alumen, alum*), Al; at. wt. 26.9815; at. no. 13; m.p. 660.2°C, b.p. 2467°C; sp. gr. 2.6989 (20°C); valence 3. Wöhler is generally accredited with isolating the metal in 1827, although an impure form was prepared by Oersted two years earlier. The method of obtaining the metal by electrolysis of alumina dissolved in cryolite was discovered in 1886 by Hall in the U.S. and independently about the same time by Heroult in France. Although aluminum occurs in larger quantities in the earth's crust than any other metal, it does not appear free. It is found as the silicate in clays, feldspars, etc., while the commercial ore is *bauxite*, an impure hydrated oxide. Its production from clay is possible but not economically feasible at present. Pure aluminum, a silvery white metal, possesses many desirable characteristics. It is light, nontoxic, has a pleasing appearance, can easily be formed, machined, or cast, has a high thermal conductivity, and has excellent corrosion resistance. It is nonmagnetic and nonsparking, stands second among metals in the scale of malleability, and sixth in ductility. It is extensively used for kitchen utensils, outside building decoration, and in thousands of industrial applications where a strong, light, easily constructed material is needed. Although its electrical conductivity is only about 60% that of copper per area of cross section, it is used in electrical transmission lines because of its light weight. Pure aluminum is soft and lacks strength, but it can be alloyed with small amounts of copper, magnesium, silicon, manganese, and other elements to impart a variety of useful properties. These alloys are of vital importance in the construction of modern aircraft and rockets. Aluminum, evaporated in a vacuum, forms a highly reflective coating for both visible light and radiant heat. These coatings soon form a thin layer of the protective oxide and do not deteriorate as do silver coatings. They have found application in coatings for telescope mirrors, in making decorative paper, packages, toys, and in many other uses. The compounds of greatest importance are aluminum oxide, the sulfate, and the soluble sulfate with potassium (alum). The oxide, alumina, occurs naturally as ruby, sapphire, corundum, and emery and is used in glassmaking. Synthetic ruby and sapphire have found application in the construction of lasers for producing coherent light. In 1856, the price of aluminum was about 90 dollars a pound, and just before Hall's discovery in 1866, about 5 dollars. The price rapidly dropped to 30 cents and has been as low as 15 cents.

AMERICIUM (the Americas), Am; at. no. 95; m.p. > 850°C; b.p. . .; sp. gr. 11.7; valence 3, 4, 5, or 6. Americium was the fourth transuranium element to be discovered; the isotope Am^{241} was identified by Seaborg, James, Morgan and Ghiorso late in 1944 at the wartime Metallurgical Laboratory (now the Argonne National Laboratory) of the University of Chicago as the result of successive neutron capture reactions by plutonium isotopes in a nuclear reactor:

$$Pu^{239}(n,\gamma)Pu^{240}(n,\gamma)Pu^{241} \xrightarrow{\beta^-} Am^{241}.$$

Since the isotope Am^{241} can be prepared in relatively pure form by extraction as a decay product over a period of years from strongly neutron-bombarded plutonium Pu^{241}, this isotope is used for much of the chemical investigation of this element. Better suited is the isotope Am^{243} due to its longer half-life (8.8×10^3 years as compared to 470 years for Am^{241}). A mixture of the isotopes Am^{241}, Am^{242}, and Am^{243} can be prepared by intense neutron irradiation of Am^{241} according to the reactions $Am^{241}(n,\gamma)$ $Am^{242}(n,\gamma)$ Am^{243}. Nearly isotopically pure Am^{243} can be prepared by a sequence of neutron bombardments and chemical separations as follows: neutron-bombardment of Am^{241} yields Pu^{242} by the reactions $Am^{241}(n,\gamma)$ $Am^{242} \xrightarrow{EC} Pu^{242}$; after chemical separation the Pu^{242} can be transformed to Am^{243} via the reactions $Pu^{242}(n,\gamma)$ $Pu^{243} \xrightarrow{\beta^-} Am^{243}$, and the Am^{243} can be chemically separated. Fairly pure Pu^{242} can be prepared more simply by very intense neutron irradiation of Pu^{239} as the result of successive neutron-capture reactions.

Americium can be obtained by reduction of americium trifluoride with barium vapor at 1000°-1200°C. The luster of freshly prepared americium metal is whiter and more silvery than plutonium or neptunium prepared in the same manner. It appears to be more malleable than uranium or neptunium and tarnishes slowly in dry air at room temperature.

The element exists in three oxidation states in aqueous solution; Am^{+3} (light salmon), AmO_2^+ (color unknown), and AmO_2^{+2} (light tan). The trivalent state is highly stable and difficult to oxidize. AmO_2^+, like plutonium, is unstable with respect to disproportionation into Am^{+3} and AmO_2^{+2}. The ion Am^{+4} is so unstable in solution that it has not yet been detected, although tetravalent solid compounds are well known. There is some evidence that Am^{+2} has been prepared in tracer experiments at very low concentrations; this would be very similar to the analogous lanthanide, europium, which can be reduced to the divalent state.

Americium dioxide, AmO_2, is the important oxide; Am_2O_3 and, as with previous actinide elements, oxides of variable compositions between $AmO_{1.5}$ and AmO_2 are known. The halides AmF_3, AmF_4, $AmCl_3$, $AmBr_3$, and AmI_3 have also been prepared.

In 1962, the A.E.C. made an initial allotment of 200 gms. of Americium-241 available for sale from the Oak Ridge National Laboratory.

ANTIMONY (L. *antimonium*), Sb, (L. *stibium*, mark); at. wt. 121.75; at. no. 51; m.p. 630.5°C; b.p. 1380°C; sp. gr. 6.691 (20°C); valence 3 or 5. Recognized in compounds by the ancients; known as a metal at the beginning of the seventeenth century and possibly before that date. Antimony is a metallic element, common, but neither abundant nor widely diffused; sometimes found native, but more frequently as the sulfide, *stibnite* (Sb_2S_3); also as antimonides and sulfantimonides of the heavy metals, and as oxides. It is extracted from the sulfide by roasting to the oxide, which is reduced by salt and scrap iron; from its oxides it is also prepared by reduction with carbon. Four allotropic forms of antimony exist: yellow antimony, black antimony, explosive antimony, and metallic or ordinary antimony. Metallic antimony is an extremely brittle metal of a flaky, crystalline texture, blue-white color and metallic luster; hardness, 3 to 3.5; not acted on by air at room temperature, but burns brilliantly when heated with formation of white fumes of oxide Sb_2O_3; it is a poor conductor of heat and electricity. This form is available commercially with a purity of 99.999+%. The metal is widely used in alloys in a percentage varying from one to twenty. It greatly increases the hardness and mechanical strength of lead. Batteries, antifriction alloys, type metal, cable sheathing, and minor products use about half of the metal. Compounds taking up the other half are oxides, sulfide, sodium antimonate, and antimony trichloride. These are used in the manufacture of flame-proofing compounds, in paints, ceramic enamels, glass and pottery. Tartar emetic (hydrated potassium antimonyl tartrate) is used as a medicine. Antimony and some of its compounds are toxic. The maximum allowable concentration of antimony dust in the air is recommended to be 0.5 mg cubic meter.

ARGON (Gr. *argon*, inactive, Ar; at. wt. 39.948; at. no. 18; freezing pt. — 189.2°C; b.p. —185.7°C; density 1.7837 g/l). Its presence in air was suspected by Cavendish in 1785; discovered by Lord Rayleigh and Sir William Ramsay in 1894. The gas is prepared by fractionation of liquid air, the atmosphere containing 0.94% argon. It is $2\frac{1}{2}$ times as soluble in water as nitrogen, having about the same solubility as oxygen; best recognized by the characteristic lines in the red end of the spectrum. It is used in electric light bulbs and in fluorescent tubes at a pressure of about 3 mm, and in filling photo tubes, glow tubes, etc. Argon is also used as an inert gas shield for arc welding and cutting, as a blanket for the production of titanium and other reactive elements, and as a protective atmosphere for growing silicon and germanium crystals. Argon is colorless and odorless, both as a gas and liquid. It is available in high-purity form. Commercial argon is available at a cost of about

10 cents per cu. ft. Although it is considered to be a very inert gas, a few compounds of argon have been reported in the literature.

ARSENIC (L. *arsenicum*, Gr. *arsenikon*, yellow orpiment—identified with *arsenikos*, male, from the belief that metals were different sexes—Arab. *az-zernikh*, the orpiment from Persian *zerni-zar*. gold–), As; at. wt. 74.9216; at. no. 33; valence +3 or +5. Elemental arsenic occurs in three solid modifications: yellow, black, and gray, with specific gravities of 1.97, 4.73, and 5.73, respectively. Gray arsenic, the ordinary stable form, has a m.p. of 817°C (28 atm.) and sublimes at 613°C. It is believed that Albertus Magnus obtained the element in 1250. In 1649 Schroeder published two methods of preparing it. Found native, in sufides *realgar* and *orpiment*, as arsenides and sulfarsenides of heavy metals and as oxide, and arsenates. *Mispickel* or arsenopyrite (FeSAs) is the most common mineral, from which on heating the arsenic sublimes leaving ferrous sulfide. The element is a steel gray, very brittle, crystalline, semi-metallic solid; it tarnishes in air and when heated is rapidly oxidized to arsenous oxide (As_2O_3) with the odor of garlic. Arsenic and its compounds are poisonous. The maximum allowable concentration of arsenic is recommended to be 0.5 mg/cu. meter of air. Arsenic is also used in bronzing, pyrotechny, and for hardening and improving the sphericity of shot. The most important compounds are white arsenic (As_2O_3), the sulfide, Paris green $3Cu(AsO_2)_2 \cdot Cu(C_2H_3O_2)_2$, calcium arsenic and lead arsenate, the last three being used as agricultural insecticides and poisons. Marsh's test makes use of the formation and ready decomposition of arsine (AsH_3). Arsenic is available in high-purity form. It is finding increasing uses as a doping agent in solid-state devices, such as transistors. Gallium arsenide is finding use as a laser material to convert electricity directly into coherent light.

ASTATINE (Gr. *astatos*, unstable) At; at. wt. 210—most stable isotope; at. no. 85; valence probably 1, 3, 5, or 7. Synthesized in 1940 by D. R. Corson, K. R. MacKenzie, and E. Segré at the University of California by bombarding bismuth with alpha-particles. The longest lived isotope, At-210, has a half-life of only 8.3 hrs. At-219, with a half-life of 0.9 min., is reported to be present in uranium ores. Astatine is the only member of the halogen family without stable isotopes. It is said to be more metallic than iodine, and like iodine, it accumulates in the thyroid gland.

BARIUM (Gr. *barys*, heavy), Ba; at. wt. 137.34; at. no. 56; m.p. 725°C; b. p. 1140°C; sp. gr. 3.5 (20°C); valence 2. Baryta was distinguished from lime by Scheele in 1774; the element was discovered by Sir Humphry Davy in 1808. It is found only in combination with other elements chiefly in *barite* or *heavy spar* (sulfate) and *witherite* (carbonate) and is prepared by electrolysis of the chloride. Barium is a metallic element, soft, and when pure is silvery-white like lead; it belongs to the alkaline earth group, resembling calcium chemically. The metal oxidizes very easily and should be kept under petroleum or other suitable oxygen-free liquids to exclude air. It is decomposed by water or alcohol. The metal is used as a "getter" in vacuum tubes. The most important compounds are the peroxide (BaO_2), chloride, sulfate, carbonate, nitrate and chlorate. Lithopone, a pigment containing barium sulfate and zinc sulfide, has good covering power, and does not darken in the presence of sulfides. The sulfate, as permanent white or *blanc fixé*, is also used in paint, in x-ray diagnostic work, and in glassmaking. The carbonate is used as a rat poison, while the nitrate and chlorate give colors in pyrotechny. The impure sulfide phosphoresces after exposure to the light. The compounds and the metal are not expensive. All barium compounds that are water or acid soluble are poisonous.

BERKELIUM (Berkeley, home of Univ. of Calif.) Bk; at. no. 97; valence 3 or 4. Berkelium, the eighth member of the actinide transition series, was discovered in December, 1949, by Thompson, Ghiorso, and Seaborg, and was the fifth transuranium element

synthesized. It was produced by cyclotron bombardment of milligram amounts of Am^{241} with helium ions at Berkeley, California. The first isotope produced had a mass number of 243 and decayed with a half-life of 4.5 hrs. by electron capture.

The chemical properties of berkelium have been studied entirely to date through the use of tracer amounts. These studies have demonstrated that berkelium exists in aqueous solutions in two oxidation states, berkelium (III) and berkelium (IV). The chemistry and solubility of compounds appears to closely follow the other transuranium elements.

The existence of Bk^{249}, with a half-life of about 300 days, makes it feasible to isolate berkelium in weighable amounts so that its properties can be investigated with macroscopic quantities.

This isotope can be prepared by the intense neutron bombardment of Cm^{244} as the result of the capture of successive neutrons by the reactions

$$Cm^{244}(n,\gamma)Cm^{245}(n,\gamma)Cm^{246}(n,\gamma)Cm^{247}(n,\gamma)Cm^{248}(n,\gamma)Cm^{249} \xrightarrow{\beta^-} Bk^{249}.$$

One of the first visible amounts of a pure berkelium compound—berkelium chloride—was produced in 1962. It weighed about 3 billionths of a gram.

BERYLLIUM (Gr. *berryllos, beryl;* also called Glucinium or Glucinum, Gr. *glykys,* sweet;) Be; at. wt. 9.0122; at. no. 4; m.p. 1278 ± 5°C; b.p. 2970^{760}°C (5mm); sp. gr. 1.848 (20°C), valence 2. Discovered as the oxide by Vauquelin in beryl and in emeralds in 1798. The metal was isolated in 1828 by Wöhler and by Bussy independently by the action of potassium on beryllium chloride. Beryl (beryllium silicate) is the most important commercial source of the element and its compounds. Most of the metal is now prepared by reducing beryllium fluoride with magnesium metal. Beryllium metal did not become readily available to industry until 1957. The metal, steel gray in color, has many desirable properties. It is one of the lightest of all metals, and has one of the highest melting points of the light metals. Its modulus of elasticity is about one third greater than that of steel. It resists attack by concentrated nitric acid, has excellent thermal conductivity, and is nonmagnetic. It has a high permeability to x-rays, and when bombarded by alpha particles, as from radium or polonium, neutrons are produced in the ratio of about 30 neutrons/million alpha particles. At ordinary temperatures beryllium resists oxidation in air, although its ability to scratch glass is probably due to the formation of a thin layer of the oxide. Beryllium is used as an alloying agent in producing beryllium copper, which is extensively used for springs, electrical contacts, spot-welding electrodes, and nonsparking tools. It is finding application as a structural material for high-speed aircraft, missiles, and spacecraft. It is used in nuclear reactors as a reflector or moderator for it has a low thermal neutron absorption cross section. It is used in gyroscopes, computer parts, and inertial guidance instruments where lightness, stiffness, and dimensional stability are required. The oxide has a very high melting point and is also used in nuclear work and ceramic applications. Beryllium and its salts are toxic and should be handled with the greatest of care. Beryllium and its compounds should not be tasted to verify the sweetish nature of beryllium (as did early experimenters). The metal, its alloys, and its salts can be handled safely if certain work codes are observed, but no attempt should be made to work with beryllium before becoming familiar with proper safeguards. The maximum allowable concentration of beryllium dust is recommended to be about 1–2 μ gms/cu. meter in working areas or .01 μ gms/cu. meter in non-working areas. Beryllium metal in vacuum cast billet form is priced roughly at 50 dollars to 100 dollars per lb., depending on the quantity ordered. Fabricated forms are more expensive. High-purity beryllium is available commercially at about 2700 dollars per lb. As techniques and supplies become more plentiful, these costs will undoubtedly be much lower.

BISMUTH (Ger. *Weisse Masse,* white mass; later *Wismuth* and *Bisemutum*). Bi; at. wt. 208.980; at no. 83; m.p. 271.3°C; b.p. 1560 ± 5^{760}°C; sp. gr. 9.747; valence 3 or 5. In early

times bismuth was confused with tin and lead. Claude Geoffroy the Younger showed it to be distinct from lead in 1753. It is a white, crystalline, brittle metal with a pinkish tinge. It occurs native. The most important ores are *bismuthinite* or *bismuth glance* (Bi_2S_3) and *bismite* (Bi_2O_3). Most of the bismuth produced in the U.S. is obtained as a by-product in refining lead, copper, tin, silver, and gold ores. Bismuth is the most diamagnetic of all metals, and the thermal conductivity is lower than any metal, except mercury. It has a high electrical resistance, and has the highest Hall effect of any metal (i.e., greatest increase in electrical resistance when placed in a magnetic field). Bismuth expands 3.32% on solidification. This property makes bismuth alloys particularly suited to the making of sharp castings of objects subject to damage by high temperatures. With other metals, such as tin, cadmium, etc., bismuth forms low-melting alloys which are extensively used for safety devices used in fire detection and extinguishing systems. When bismuth is heated in air it burns with a blue flame forming yellow fumes of the oxide. The metal is also used as a thermocouple material (has highest negativity known), and has found recent application as a carrier for U^{235} or U^{233} fuel in atomic reactors. Its soluble salts are characterized by forming insoluble basic salts on the addition of water—a property sometimes used in detection. Bismuth subnitrate and subcarbonate are used in medicine. High-purity bismuth metal is available for about 5 dollars per lb.

BORON (Ar. *Būraq*, Pers. *Būrah*), B; at. wt. 10.811; at. no. 5; m.p. 2300°C; b.p. sublimes 2550°C; sp. gr. of crystals 2.34, of amorphous variety 2.37; valence 3. Discovered in 1808 by Sir Humphry Davy and by Gay-Lussac and Thenard. The element is not found free in nature, but occurs as orthoboric acid usually in certain volcanic spring waters and as borates in *borax* and *colemanite*. *Ulexite*, another boron mineral, is interesting as it is nature's own version of "fiber optics." By far the most important source of boron is the mineral *rasorite*, also known as *kernite*, found in the Mojave desert of California. High-purity crystalline boron may be prepared by the vapor phase reduction of boron trichloride or tribromide with hydrogen on electrically heated filaments. The impure, or amorphous boron, a brownish-black powder, can be obtained by heating the trioxide with magnesium powder. Boron of 99.9999% purity has been produced and is available commercially. Elemental boron has an energy band gap of 1.50 to 1.56 electron volts, which is higher than that of either silicon or germanium. It has interesting optical characteristics, transmitting portions of the infra red, and is a poor conductor of electricity at room temperature, but a good conductor at high temperature. The most important compounds of boron are boric, or boracic acid widely used as a mild antiseptic, and borax ($Na_2B_4O_7{\cdot}10H_2O$), which serves as a cleansing flux in welding and as a water softener in washing powders. Boron compounds are used in production of enamels for covering steel of refrigerators, washing machines, and like products. Boron compounds are also extensively used in the manufacture of borosilicate glasses. The isotope boron 10 is used as a control for nuclear reactors, as a shield for nuclear radiation, and in instruments used for detecting neutrons. Boron nitride has remarkable properties and can be used to make a material as hard as diamond. It also has lubricating properties similar to graphite. The hydrides are easily oxidized with considerable energy liberation, and are being studied for use as rocket fuels.

BROMINE (Gr. *bromos*, stench), Br; at. wt. 79.909; at. no. 35; m.p. −7.2°C; b.p. 58.78°C; density of gas 7.59 g/l, liquid 3.12 (20°C); valence 1, 3, 5, or 7. Discovered by Balard in 1826, but not prepared in quantity until 1860. A member of the halogen group of elements, it is obtained from natural brines from wells in Michigan and West Virginia and from sea water by displacement with chlorine; electrolysis might be used. Bromine is the only liquid nonmetallic element. It is a heavy, mobile, reddish-brown liquid, volatilizing readily at room temperature to a red vapor with a strong disagreeable odor, resembling chlorine, and having a very irritating effect on the eyes and throat; it is readily soluble in water or carbon disulfide, forming a red solution; it is less active than chlorine but more so

than iodine; it unites readily with many elements and has a bleaching action; when spilled on the skin it produces painful sores. About 80% of the bromine output in the U.S. is used in the production of ethylene dibromide, a lead scavenger used in making gasoline antiknock compounds. Bromine is also used in making fumigants, flameproofing agents, water purification compounds, dyes, medicinals, sanitizers, inorganic bromides for photography, etc. Organic bromides are also important.

CADMIUM (L. *cadmia;* Gr. *kadmeia*—ancient name for calamine, zinc carbonate) Cd; at. wt. 112.40; at. no. 48; m.p. 320.9°C; b.p. 765°C; sp. gr. 8.65 (20°C); valence 2. Discovered by Stromeyer in 1817 from an impurity in zinc carbonate. Cadmium most often occurs in small quantities associated with zinc ores, such as *sphalerite* (ZnS). *Greenockite* (CdS) is the only mineral of any consequence bearing cadmium. Almost all cadmium is obtained as a by-product in the treatment of zinc, copper, and lead ores. It is a soft, bluish-white metal which is easily cut with a knife. It is similar in many respects to zinc. It is a component of some of the lowest melting alloys; it is used in bearing alloys with low coefficients of friction and great resistance to fatigue; it is used extensively in electroplating, which accounts for about 60% of its use. It is also used in many types of solder, for standard E.M.F. cells, for batteries, and as a barrier to control atomic fission. It forms a number of salts of which the sulfate is the most common; the sulfide is used as a yellow pigment. Cadmium and solutions of its compounds are toxic. Failure to appreciate the toxic properties of cadmium may cause workers to be unwittingly exposed to dangerous fumes. The recommended maximum allowable concentration of cadmium vapor in air is 0.1 mg/cu. meter. The current price of cadmium is about 2 dollars per pound. It is available in high-purity form.

CALCIUM (L. *calx,* lime), Ca; at. wt. 40.08; at. no. 20; m.p. 842–8°C; b.p. 1487°C; sp. gr. 1.55 (20°C); valence 2. Though lime was prepared by the Romans in the first century under the name calx, not until 1808 was the metal discovered. After learning that Berzelius and Pontin prepared calcium amalgam by electrolyzing lime in mercury, Davy was able to isolate the impure metal. Calcium is a metallic element, fifth in abundance in the earth's crust, of which it forms more than three per cent. It is an essential constituent of leaves, bones, teeth and shells. Never found in nature uncombined, it occurs abundantly as *limestone* ($CaCO_3$), *gypsum* ($CaSO_4 \cdot 2H_2O$) and *fluorite* (CaF_2); *apatite* is the fluophosphate or chlorophosphate of calcium. The metal is a silvery color, rather hard, and is prepared by electrolysis of the fused chloride to which calcium fluoride is added to lower the melting point. Chemically it is one of the alkaline earth elements; it readily forms a white coating of nitride in air, reacts with water, burns with a yellow red flame, forming largely the nitride. The metal is used as a reducing agent in preparing other metals, such as thorium, uranium, zirconium, etc., and is used as a deoxidizer, desulfurizer, or decarburizer for various ferrous and nonferrous alloys. It is also used as an alloying agent for aluminum, beryllium, copper, lead and magnesium alloys, and serves as a "getter" for residual gases in vacuum tubes, etc. Its natural and prepared compounds are widely used. Quicklime (CaO), made by heating limestone and changed into slaked lime by the careful addition of water, is the great cheap base of chemical industry with countless uses. Mixed with sand it hardens as mortar and plaster by taking up carbon dioxide from the air. Calcium from limestone is an important element in Portland cement. The solubility of the carbonate in water containing carbon dioxide causes the formation of caves with stalactites and stalagmites and hardness in water. Other important compounds are the carbide (CaC_2), chloride ($CaCl_2$), cyanamide ($Ca(CN_2)$), hypochlorite ($Ca(OCl)_2$), nitrate ($Ca(NO_3)_2$), and sulfide (CaS).

CALIFORNIUM (State and University of California; Cf; at. no. 98) Californium, the sixth transuranium element to be discovered, was produced by Thompson, Street, Ghiorso,

and Seaborg in January, 1950 by bombarding microgram quantities of Cm^{242} with 35 MeV helium ions in the Berkeley 60-inch cyclotron. Like berkelium, its chemical properties have been studied solely with tracer amounts. Californium (III) is the only ion stable in aqueous solutions, all attempts to reduce or oxidize californium (III) having failed. The isotope Cf^{249} results from the beta decay of Bk^{249} while the heavier isotopes are produced by intense neutron irradiation by the reactions.

$Bk^{249}(n,\gamma)\ Bk^{250} \xrightarrow{\beta^-} Cf^{250}$ and $Cf^{249}(n,\gamma)Cf^{250}$ followed by $Cf^{250}(n,\gamma)\ Cf^{251}(n,\gamma)Cf^{252}$.

The existence of the isotopes Cf^{249}, Cf^{250}, Cf^{251}, and Cf^{252} makes it feasible to isolate californium in weighable amounts so that its properties can be investigated with macroscopic quantities. Californium 252 is a very strong neutron emitter. One microgram releases 170 million neutrons per minute which presents biological hazards. In 1960 a few tenths of a microgram of californium trichloride $CfCl_3$, californium oxychloride, CfOCl, and californium oxide, Cf_2O_3, were prepared. Pure californium metal has not yet been produced. Eventually, it is thought that gram quantities of californium may be prepared.

It has been postulated that californium may be produced in certain stellar explosions, called supernovae, for the radioactive decay of californium-254 (55-day half-life) agrees with the characteristics of the light curves of such explosions observed through telescopes.

CARBON (L. *carbo*, charcoal), C; at. wt. 12.01115; at. no. 6; m.p. 3550°C, sublimes above 3500°C; b.p. 4827°C; sp.g. amorphous 1.8–2.1, graphite 1.9–2.3, diamond 3.15–3.53 (depending on variety); gem diamond 3.513 (25°C); valence 2, 3, or 4. Carbon, an element of prehistoric discovery, is very widely distributed in nature. It is found in abundance in the sun, stars, comets, and atmospheres of most planets. Carbon in the form of microscopic diamonds is found in some meteorites. The energy of the sun and stars can be attributed at least in part to the well-known carbon-nitrogen cycle. Carbon is found free in nature in three allotropic forms: amorphous, graphite, and diamond. Graphite is one of the softest known materials while diamond is one of the hardest. In combination, carbon is found as carbon dioxide in the atmosphere of the earth and dissolved in all natural waters. It is a component of great rock masses in the form of carbonates of calcium (limestone), magnesium, and iron. Coal, petroleum, and natural gas are chiefly hydrocarbons. Carbon is unique among the elements in the vast number and variety of compounds it can form. With hydrogen, oxygen, and nitrogen, and other elements, it forms almost an infinite number of compounds, carbon atom often being linked to carbon atom. There are upwards of a million or more known carbon compounds, many thousands of which are vital to organic and life processes. Without carbon, the basis for life would be impossible. While it has been thought that silicon might take the place of carbon in forming a host of similar compounds, it is now not possible to form stable compounds with very long chains of silicon atoms. Some of the most important compounds of carbon are: carbon dioxide (CO_2), carbon monoxide (CO), carbon disulfide (CS_2), chloroform ($CHCl_3$), carbon tetrachloride (CCl_4), methane (CH_4), ethylene (C_2H_4), acetylene (C_2H_2), benzene (C_6H_6), ethyl alcohol (C_2H_5OH), acetic acid (CH_3COOH), and their derivatives. Carbon has five isotopes. In 1961 the International Union of Pure and Applied Chemistry adopted the isotope carbon-12 as the basis for atomic weights. Carbon-14, an isotope with a half-life of 5700 yrs, has been widely used to date such materials as wood, archeological specimens, etc.

CERIUM (named for the asteroid *Ceres*, which was discovered in 1801 only two years before the element), Ce; at. wt. 140.12; at. no. 58; m.p. 795°C; b.p. 3468°C; sp. gr. 6.67 to 8.23 (depending on allotropic form); valence 3 or 4. Discovered in 1803 by Klaproth and by Berzelius and Hisinger; metal prepared by Hillebrand and Norton in 1875. Cerium is the most abundant of the metals of the so-called rare earths; it is found in a number of minerals including *monazite*, *bastnaesite*, *cerite* and *samarskite*. Monazite and bastnaesite are presently the two most important sources of cerium. Large deposits of monazite found

on the beaches of Travancore, India, in river sands in Brazil, and deposits of bastnaesite in Southern California will supply cerium, thorium and the other rare-earth metals for many years to come. The metal exists in four allotropic states. It is prepared by the electrolysis of the chloride. Cerium is an iron-gray lustrous metal. It is malleable and stable in dry air, but slowly decomposed by cold, and rapidly by hot water. The pure metal is likely to ignite if scratched with a knife. Ceric salts are orange-red or yellowish; cerous salts are usually white. Cerium is a component of misch metal, which is extensively used in the manufacture of pyrophoric alloys for cigarette lighters, etc. While cerium is not radioactive, the impure commercial grade may contain traces of thorium, which is radioactive. The oxide is an important constituent of incandescent gas mantles; as ceric sulfate it finds extensive use as a volumetric oxidizing agent in quantitative analysis. Cerium compounds are used in the manufacture of glass, both as a component and as a decolorizer. The oxide is finding increased use as a glass polishing agent instead of rouge, for it is much faster than rouge in polishing glass surfaces. Cerium, with other rare earths, is used in carbon-arc lighting, especially in the motion picture industry. It also finds use in metallurgical and nuclear applications. Commercial cerium metal costs about 10 dollars to 30 dollars/lb. depending on quantity and purity. In small lots, 99.9% cerium costs about 40 cents/gm.

CESIUM (L. *caesius*, sky blue), Cs; at. wt. 132.905; at. no. 55; m.p. 28.5°C; b.p. 690°C; sp. gr. 1.873 (20°C) valence 1. Cesium was discovered spectroscopically in 1860 in mineral water from Dürkheim, by Bunsen and Kirchhoff. Cesium, an alkali metal, occurs in *lepidolite*, *pollucite* (a hydrated silicate of aluminum and cesium) and other sources. It is isolated by electrolysis of the fused cyanide. The metal is characterized by a spectrum containing two bright lines in the blue along with several others in the red, yellow and green. It is silvery-white, soft, and ductile. It is the most electropositive and most alkaline element. Cesium, gallium and mercury are the only three metals that are liquid at room temperature. Cesium reacts explosively with cold water, and reacts with ice at temperatures above −116°C. Cesium hydroxide, the strongest base known, attacks glass. Because of its great affinity for oxygen the metal is used as a "getter" in radio tubes. It is also used in photo-electric cells, as well as a catalyst in the hydrogenation of certain organic compounds. The metal has recently found application in ion propulsion systems. Although these are not useable in the earth's atmosphere, 1 lb. of cesium in outer space theoretically will propel a vehicle 140 times as far as the burning of the same amount of any known liquid or solid. Its chief compounds are the chloride and the nitrate. The present price of cesium is about 100 dollars to 150 dollars/lb., depending on quantity and purity.

CHLORINE (Gr. *chloros*, greenish-yellow), Cl; at. wt. 35.453; at. no. 17; f.p. −100.98°C; b.p. −34.6°C; density 3.214 g/l, sp. gr. 1.56 (−33.6°C); valence 1, 3, 5, or 7. Discovered in 1774 by Scheele, who thought it contained oxygen; named in 1810 by Davy, who insisted it was an element. In nature it is found in the combined state only, chiefly with sodium as common salt (NaCl), *carnallite* ($KMgCl_3 \cdot 6H_2O$), and *sylvite* (KCl). It is a member of the halogen (salt forming) group of elements and is obtained from chlorides by the action of oxidizing agents and more often by electrolysis; it is a greenish-yellow gas, combining directly with nearly all elements. At 10°C one volume of water dissolves 3.10 volumes of chlorine, at 30° only 1.77 volumes. Chlorine is widely used in making many every-day products. It is used for producing safe drinking water the world over. Even the smallest water supplies are now usually chlorinated. It is also extensively used in the production of paper products, dyestuffs, textiles, petroleum products, medicines, antiseptics, insecticides, foodstuffs, solvents, paints, plastics, and many other consumer products. Most of the chlorine produced is used in the manufacture of chlorinated compounds for sanitation, pulp bleaching, disinfectants, and textile processing. Further use is in the manufacture of

chlorates, chloroform, carbon tetrachloride and in the extraction of bromine. Organic chemistry demands much from chlorine, both as an oxidizing agent and in substitution, since it often brings desired properties in an organic compound when substituted for hydrogen, as in one form of synthetic rubber. Chlorine is a respiratory irritant. The gas irritates the mucous membranes and the liquid burns the skin. As little as 3.5 ppm. can be detected as an odor, and 1000 ppm. is likely to be fatal after a few deep breaths. It was used as a war gas in 1915. The recommended maximum allowable concentration in air is about 1 ppm. for prolonged exposure.

CHROMIUM (Gr. *chroma*, color), Cr; at. wt. 51.996; at. no. 24; m.p. 1890°C; b.p. 2482°C; sp. gr. 7.18–7.20 (20°C); valence, 2, 3, or 6. Discovered in 1797 by Vauquelin, who prepared the metal the next year. Chromium is a steel gray, lustrous, hard metal that takes a high polish. The principal ore is *chromite* ($FeO{\cdot}Cr_2O_3$), which is found in Southern Rhodesia, Russia, Republic of South Africa, Cuba, New Caledonia, and the Philippines. The metal is produced by reducing the oxide with aluminum. Chromium is used to harden steel, to manufacture stainless steel, and to form many very useful alloys. Much is used in plating to produce a hard, beautiful surface and to prevent corrosion. Chromium is used to give glass an emerald green color. It finds wide use as a catalyst. All compounds of chromium are colored; the most important are the chromates of sodium and potassium (K_2CrO_4) and the dichromates ($K_2Cr_2O_7$) and the potassium and ammonium chrome alums, as $KCr(SO_4)_2{\cdot}12H_2O$. The dichromates are used as oxidizing agents in quantitative analysis, also in tanning leather. Other compounds are of industrial value; lead chromate is chrome yellow, a valued pigment. Chromium compounds are used in the textile industry as mordants, and by the aircraft and other industries for anodizing aluminum. The refractory industry has found chromite useful for forming bricks and shapes, as it has a high melting point, moderate thermal expansion, and stability of crystalline structure. Hexavalent chromium compounds are toxic. The recommended maximum allowable concentration of dusts and mists in air, measured as CrO_3,is 0.1 mg./cu.m for daily 8-hr. exposure. Chromium is available in high-purity form.

COBALT (*Kobold*, from the German, goblin or evil spirit), Co; at. wt. 58.9332; at. no. 27; m.p. 1495°C; b.p. 2900°C; sp. gr. 8.9 (20°C); valence 2 or 3. Discovered by Brandt about 1735. Cobalt occurs in the minerals *cobaltite*, *smaltite*, and *erythrite*, and is often associated with nickel, silver, lead, copper, and iron ores, from which it is most frequently obtained as a by-product. It is also present in meteorites. Cobalt is a brittle, hard metal, closely resembling iron and nickel in appearance. It has a magnetic permeability of about two-thirds that of iron. It is alloyed with iron, nickel, and other metals to make Alnico, an alloy of unusual magnetic strength with many important uses. Stellite alloys, containing cobalt, chromium, and tungsten, are used for high-speed, heavy-duty, high-temperature cutting tools, and for dies. Cobalt is also used in other magnet steels and stainless steels, and in alloys used in jet turbines and turbo-superchargers. The metal is used in electroplating because of its appearance, hardness, and resistance to oxidation. The salts have been used for centuries for the production of brilliant and permanent blue colors in porcelain, glass, pottery, tiles and enamels. It is the principal ingredient in *Serves* and *Thenard's blue*. A solution of the chloride ($CoCl_2{\cdot}6H_2O$) is used as sympathetic ink. The cobalt ammines are of interest; the oxide and the nitrate are important. Cobalt carefully used in the form of the chloride, sulfate, acetate, or nitrate has been found effective in correcting a certain mineral deficiency disease in animals. Soils should contain 0.13 to 0.30 ppm. of cobalt for proper animal nutrition. Cobalt-60, an artificial isotope, is an important gamma ray source, and is extensively used as a radio-therapeutic agent. Single compact sources of Cobalt-60, are readily available and have an equivalent gamma ray output equal to thousands of grams of radium. The cost of Cobalt-60 is about 2 dollars/curie.

COLUMBIUM (see Niobium).

COPPER (L. *cuprum*, from the island of Cyprus), Cu; at. wt. 63.54; at. no. 29; m.p. 1083.0 ± 0.1°C; b.p. 2595°C; sp. gr. 8.96 (20°C); valence 1 or 2. The discovery of copper dates from prehistoric times; it is said to have been mined for more than 5000 years. It is one of man's most important metals. Copper is reddish-colored, takes on a bright metallic luster and is malleable, ductile, and a good conductor of heat and electricity (second only to silver in electrical conductivity). The electrical industry is one of the greatest users of copper. Copper occasionally occurs native, and is found in many minerals, such as *cuprite, malachite, azurite, chalcopyrite,* and *bornite;* the most important of these compounds are sulfides, oxides, and carbonates. From these it is obtained by smelting, leaching or electrolysis. Its alloys, brass and bronze, long used, are still very important; all American coins are copper alloys; monel and gun metals also contain copper. The most important compounds are the oxide and the sulfate, blue vitriol; the latter has wide use as an agricultural poison and as an algicide in water purification. Copper compounds are widely used in analytical chemistry, as Fehling's solution in tests for sugar. High-purity copper (99.999+%) is available commercially.

CURIUM (Pierre and Marie Curie), Cm; at. no. 96; sp. g. about 7. Although curium follows americium in the periodic system, it was actually known before americium and was the third transuranium element to be discovered. It was identified by Seaborg, James, and Ghiorso in 1944 at the wartime Metallurgical Laboratory in Chicago as a result of helium-ion bombardment of Pu^{239} in the Berkeley, California, 60-inch cyclotron. The isotope Cm^{242} (half-life 162.5 days), produced from Am^{241} by the reactions $Am^{241}(n,\gamma)Am^{242} \xrightarrow{\beta^-} Cm^{242}$, has been used for much work with macroscopic quantities, although this is difficult due to the extremely high specific alpha activity. Cm^{244} is an excellent isotope for the investigation of curium in weighable amounts because it has a half-life of 19 years and can be prepared in fairly pure form by a sequence of neutron bombardments and chemical separations as follows: The neutron-bombardment of Am^{241} yields Pu^{242} by the reactions $Am^{241}(n,\gamma)$ $Am^{242} \xrightarrow{EC} Pu^{242}$; after chemical separation the Pu^{242} can be transformed to Am^{243} via the reactions $Pu^{242}(n,\gamma)$ $Pu^{243} \xrightarrow{\beta^-} Am^{243}$. Fairly pure Pu^{242} can be prepared more simply by very intense neutron irradiation of Pu^{239} as the result of successive neutron-capture reactions. The Am^{243} can be chemically separated and finally transmuted to Cm^{244} through neutron bombardment by the reactions $Am^{243}(n,\gamma)$ $Am^{244} \xrightarrow{\beta^-} Cm^{244}$. Further neutron bombardment of Cm^{244} produces higher-mass isotopes of longer half-life which are even better for use in the investigation of curium. Curium metal has been isolated, is silvery in appearance, and closely resembles the other actinide metals. The metal is about as malleable as plutonium prepared under the same conditions. It retains its bright appearance in a dry atmosphere of nitrogen for a few hours, but gradually tarnishes and badly corrodes after 24 hours. Also, in common with other metals, it can be prepared by heating curium trifluoride with barium vapor at 1275°C. The only oxidation state in aqueous solutions which has been definitely identified is Cm^{+3}, although a solid, black CmO_2 has been prepared. Both Cm_2O_3 and CmF_3 are white compounds. The general trend of decreasing stability of higher oxidation states with increasing atomic number indicates that oxidation states of curium higher than curium (III) probably is not stable in aqueous solutions. It has further been demonstrated that curium (III) cannot be reduced in aqueous solutions. The experimentally determined magnetic susceptibility of CmF_3 is in good agreement with the value expected for the electronic structure $5f^7$ in curium (III), assuming a Russell-Saunders coupling scheme. In 1960, it was reported that about 12kg. of plutonium was put into a reactor at the Savannah River facility for 2 to 3 yr. neutron bombardment. From this it was hoped to get 100 gms. or so of curium. Some of this would be bombarded to

produce heavier elements. About 100 mg. of curium have already been distributed to various national laboratories for research purposes.

DEUTERIUM, an isotope of hydrogen—see Hydrogen.

DYSPROSIUM (Gr. *dysprositos*, hard to get at), Dy; at. wt. 162.50; at. no. 66; m.p. 1407°C; b.p.2600°C; sp. gr. 8.536; valence 3. Discovered but not isolated in 1886 by Lecoq de Boisbaudran. Dysprosium occurs along with other so-called rare-earth or "lanthanide" elements in a variety of minerals, such as *xenotime, fergusonite, gadolinite, euxenite, polycrase* and *blomstrandine.* The most important sources, however, are from *monazite and bastnaesite.* Dysprosium has only been isolated within recent years. Some very pure rare-earth metals, including dysprosium, can be prepared by reduction of the rare-earth salts with calcium followed by volatilization of the calcium from the resulting rare-earth calcium alloy. Dysprosium, as well as certain other rare-earth metals, can also be made by reducing the anhydrous fluoride or chloride with calcium, sodium, potassium, etc. Dysprosium, like the other rare-earth metals, has a metallic, bright silver luster. In moist air, the metal tarnishes with the formation of a loosely adhering oxide film which spalls off and exposes more metal surface to oxidation. The metal reacts slowly with water and is soluble in dilute acids. The metal is soft enough to be cut with a knife and can be machined without sparking if overheating is avoided. Small amounts of impurities can greatly affect the physical properties of the rare earth metals. While dysprosium has not yet found many applications, its thermal neutron absorption cross-section and high melting point suggest metallurgical uses in nuclear control applications for alloying with special stainless steels. Dysprosium oxide is a white powder. In small lots, dysprosium metal (99+% pure) costs less than one dollar per gram.

EINSTEINIUM (Albert Einstein), Es; at. no. 99. Einsteinium, the seventh transuranium element of the actinide series to be discovered, was identified by Ghiorso and coworkers at Berkeley in December 1952 in debris from the first large thermonuclear or "hydrogen" bomb explosion, which took place in the Pacific in November 1952. The isotope produced was the 20-day Es^{253}, originating from beta decay of U^{253} and daughters. Its chemical properties have been studied solely with tracer amounts and indicate that the (III) oxidation state may be the only one which exists in aqueous solution. The isotope Es^{253} and heavier isotopes have been produced by intense neutron bombardment of lower elements, such as plutonium, by a process of successive neutron capture interspersed with beta decays until these mass numbers and atomic numbers are reached. In 1961 a sufficient amount of einsteinium was produced by this method to permit separation of a macroscopic amount of Es^{253}. This sample weighed about .01 microgram. A special magnetic-type balance was used in making this determination. Es^{253} so produced was used to produce mendelevium (Element 101). Several isotopes of einsteinium exist. Es^{254} is relatively long-lived, and may be used to prepare larger weighable quantities of the element.

ELEMENT 102. Element 102 was unambiguously discovered and identified in April 1958 by A. Ghiorso, T. Sikkeland, J. R. Walton, and G. T. Seaborg, who prepared the three-second alpha-emitting isotope 102^{254} by bombarding Cm^{246} with C^{12} nuclei, accelerated in a heavy-ion linear accelerator (HILAC), and collecting the recoiling transmutation product atoms. The alpha decay daughter was shown by its ion exchange behavior to be an isotope of fermium (element 100); hence the parent was an isotope of element 102. The chemical properties of element 102 are not known. (In 1957, workers from the Argonne National Laboratory, The Atomic Energy Research Establishment of Harwell, England, and the Nobel Institute for Physics in Stockholm announced the discovery of an isotope of element 102, as a result of bombarding Cm^{244} with C^{13} nuclei in the Nobel Institute's cyclotron. This isotope was said to have a half-life of about 10 min., and to de-

cay by emitting 8.5 m.e.v. alpha particles. The name Nobelium, and the symbol No was proposed, and the name was accepted by the Commission on Atomic Wts. of the International Union of Pure and Applied Chemistry. The acceptance was apparently premature, for all attempts to duplicate the Stockholm experiment in the U.S. and U.S.S.R. have failed, even though much more sensitive research tools were used than in the original experiment.

ERBIUM (*Ytterby*, a town in Sweden), Er; at. wt. 167.26; at. no. 68; m.p. 1497°C; b.p. 2900°C; sp. gr. 9.051; valence 3. Discovered in 1843 by Mosander, who reportedly isolated the element as a dark gray metallic powder. Erbium, one of the so-called rare-earth elements of the lanthanide series, is found in the minerals mentioned under dysprosium above. The element has been isolated in pure form only in recent years. The pure metal is soft and malleable, and has a bright, silvery, metallic luster. As with other rare-earth metals, its properties depend to a certain extent on the impurities present. The metal is fairly stable in air and does not oxidize as rapidly as some of the other rare-earth metals. Erbium can be produced by electrolysis of the fused anhydrous chloride. Recent production techniques, using ion-exchange reactions, have resulted in much lower prices of the rare-earth metals and their compounds in recent years. The cost of 99.9+% erbium metal is about one dollar per gram in small quantities. Erbium is finding nuclear and metallurgical uses. Added to vanadium, for example, erbium lowers the hardness and improves workability. Most of the rare earth oxides have sharp absorption bands in the visible, ultraviolet, and near infrared. This property, associated with the electronic structure, gives beautiful pastel colors to many of the rare-earth salts. Erbium oxide gives a pink color and is used as a colorant in glasses and porcelain enamel glazes.

EUROPIUM (Europe), Eu; at. wt. 151.96; at. no. 63; m.p. 826°C; b.p. 1439°C; sp. gr. 5.259; valence 2 or 3. Europium was discovered and prepared in the form of the oxide by Demarcay in 1896. It occurs in *monazite*, *bastnaesite*, and other minerals along with other rare-earth elements of the lanthanide series. It has been identified spectroscopically in the sun and certain stars. The pure metal was not isolated until recent years. Europium has a relatively low vapor pressure and its oxide can be reduced with lanthanum metal using special techniques. It is silvery-white in appearance and has a metallic luster. As with other rare-earth metals, except for lanthanum, europium ignites in air at about 150 to 180°C. Europium is about as hard as lead and is quite ductile. It is the most reactive of the rare-earth metals, quickly oxidizing in air; it resembles calcium in its reaction with water. Europium isotopes are good neutron absorbers and are being studied for use in nuclear control applications. Europium-doped plastic has been used as a laser material. With the development of ion-exchange techniques and special processes, the cost of the metal has been greatly reduced recently. Europium is one of the rarest and most costly of the rare-earth metals. It is priced at about 4 dollars to 8 dollars/gram, depending on purity and quantity.

FERMIUM (Enrico Fermi), Fm; at. no. 100. Fermium, the eighth transuranium element of the actinide series to be discovered, was identified by Ghiorso and co-workers early in 1953 in the debris from a thermonuclear explosion in the Pacific in work involving the University of California Radiation Laboratory, the Argonne National Laboratory, and the Los Alamos Scientific Laboratory. The isotope produced was the 16-hour Fm^{255}, originating from the beta decay of U^{255} and daughters. Its chemical properties have been studied solely with tracer amounts, and in normal aqueous media only the (III) oxidation state appears to exist. The isotope Fm^{254} and heavier isotopes can be produced by intense neutron irradiation of lower elements, such as plutonium, by a process of successive neutron capture interspersed with beta decays until these mass numbers and atomic numbers are reached. Nine isotopes of fermium are known to exist. Fm^{252}, with a half-life of about

23 hrs., is the longest lived. Fm^{250}, with a half-life of 30 min., has been shown to be a product of decay of Element 102^{254}. It was by chemical identification of Fm^{250} that it was certain that Element 102 had been produced.

FLUORINE (L. and F. *fluere*, flow, or flux), F; at. wt. 18.9984; at. no. 9; f.p. −219.62°C (1 atm.); b.p. − 188.14°C (1 atm.); density 1.696 g/l (0°C, 1 atm.); sp. gr. of liquid 1.108 at b.p.; valence 1. In 1529, Georgius Agricola described the use of fluorspar as a flux, and as early as 1670 Schwandhard found that glass was etched when exposed to fluorspar treated with acid. Scheele and many later investigators, including Davy, Gay-Lussac, Lavoisier, and Thenard, experimented with hydrofluoric acid, some experiments ending in tragedy. The element was finally isolated in 1886 by Moisson after nearly 74 years of continuous effort. Fluorine occurs chiefly in *fluorspar* (CaF_2) and *cryolite* (Na_3AlF_6), but is rather widely distributed in other minerals. It is a member of the halogen family of elements, and obtained by electrolyzing a solution of potassium hydrogen fluoride in anhydrous hydrogen fluoride in a vessel of metal or transparent fluorspar. Modern commercial production methods are essentially variations on the procedures first used by Moisson. Fluorine is the most electronegative and reactive of all elements. It is a pale yellow, corrosive gas, which reacts with practically all organic and inorganic substances. Finely divided metals, glass, ceramics, carbon, and even water burns in fluorine with a bright flame. Until World War II, there was no commercial production of elemental fluorine. The atom-bomb project and nuclear energy applications, however, made it necessary to produce large quantities. Safe handling techniques have now been developed and it is possible at present to transport liquid fluorine by the ton. Fluorine and its compounds are used in producing uranium (from the hexafluoride) and more than 100 commercial fluorochemicals, including many well-known high-temperature plastics. Hydrofluoric acid is extensively used for etching the glass of light bulbs, etc. Fluorochloro hydrocarbons are extensively used in air conditioning and refrigeration. It has been suggested that fluorine can be substituted for hydrogen wherever it occurs in organic compounds, which could lead to an astronomical number of new fluorine compounds. The presence of fluorine as a soluble fluoride in drinking water to the extent of 2 ppm may cause mottled enamel in teeth, when used by children acquiring permanent teeth; in smaller amounts, however, fluorides are said to be beneficial and used in water supplies to prevent dental cavities. Elemental fluorine is being studied as a rocket propellant as it has an exceptionally high specific impulse value. Although compounds of fluorine with rare gases were reported many years ago, their existence now seems to be confirmed. Fluorides of xenon, radon, and krypton are among those recently reported. Elemental fluorine and the fluoride ion are highly toxic. The free element has a characteristic pungent odor, detectable in concentrations as low as 20 parts per billion, which is below the safe working level. The recommended maximum allowable concentration for a daily 8-hr. exposure is 0.1 ppm.

FRANCIUM (France), Fr; at. no. 87; at. wt. 223 (most stable isotope); valence 1. Discovered in 1939 by Mlle. Marguerite Perey of the Curie Institute, Paris. Francium, the last member of the alkali metal series, occurs as a result of an alpha disintegration of actinium. It can also be made artificially by bombarding thorium with protons. While it occurs naturally in uranium minerals, there is probably less than an ounce of francium at any time in the total crust of the earth. It has the highest equivalent weight of any element, and is the most unstable of the first 101 elements of the periodic system. There are possibly as many as 19 isotopes of francium; the longest lived, Fr^{223}(AcK) a daughter of Ac^{227}, has a half-life of 21 minutes. The chemistry of francium can only be studied on the tracer level.

GADOLINIUM (*gadolinite*—a mineral named for Gadolin, a Finnish chemist), Gd; at. wt. 157.25; at. no. 64; m.p. 1312°C; b.p. ~3000°C; sp. gr. 7.895 and 7.8 (depending on

form); valence 3. Gadolinia, the oxide of gadolinium, was separated by Marignac in 1880 and by Lecoq de Boisbaudran in 1886. The element was named for the mineral from which this rare-earth was originally obtained. Gadolinium is found in several other minerals, including *monazite* and *bastnaesite*, which are of commercial importance. The element has been isolated only in recent years. With the development of ion-exchange techniques, the availability and price of gadolinium and the other rare-earth metals has greatly improved. The metal can be prepared in several ways, among which is the reduction of the anhydrous fluoride with metallic calcium. Like other related rare-earth metals, it is silvery-white, has a metallic luster, and is malleable and ductile. The metal is relatively stable in dry air, but in moist air, it tarnishes with the formation of a loosely adhering oxide film which spalls off and exposes more surface to oxidation. The metal reacts slowly with water and is soluble in dilute acid. Gadolinium has the highest neutron absorption cross-section of any known element (46,000 barns) and therefore may be useful for nuclear control rods and as a nuclear shield. It has been used in making gadolinium yttrium garnets, which have microwave applications. The metal has unusual superconductive properties. As little as 1% gadolinium has been found to improve the workability and resistance of iron, chromium, and related alloys to high temperatures and oxidation. Gadolinium ethyl sulfate has extremely low noise characteristics and may find use in duplicating the performance of h.f. amplifiers, such as the maser. The metal is ferromagnetic. The price of the metal is about 200 dollars/lb.

GALLIUM (L. *Gallia*, France), Ga; at. wt. 69.72; at. no. 31; m.p. 29.78°C; b.p. 2403°C; sp. gr. 5.907 (20°C); valence 2 or 3. Predicted and described by Mendeleev as ekaaluminum, and discovered spectroscopically by Lecoq de Boisbaudran in 1875, who in the same year obtained the free metal by electrolysis of a solution of the hydroxide in KOH. Gallium is often found as a trace element in *diaspore*, *sphalerite*, *germanite*, *bauxite*, and *coal*. Some flue dusts from burning coal have been shown to contain as much as 1.5% gallium. It is the only metal, except for mercury, cesium, and rubidium, which can be liquid near room temperatures; this makes possible its use in high-temperature thermometers. It has one of the longest liquid range of any metal and has a low vapor pressure even at high temperatures. Ultra-pure gallium has a beautiful, silvery appearance and the solid metal exhibits a conchoidal fracture similar to glass. The metal expands 3.1% on solidifying; therefore, it should not be stored in glass or metal containers as they may break as the metal solidifies. Gallium wets glass or porcelain, and forms a brilliant mirror when it is painted on glass. It has found recent use in doping semiconductors and producing solid-state devices, such as transistors. Gallium arsenide is capable of converting electricity directly into coherent light. Gallium readily alloys with most metals, and has been used as a component in low-melting alloys. Its toxicity appears to be of a low order, but should be handled with care until more data are forthcoming. The metal can be supplied in ultra-pure form (99.99999+%).

GERMANIUM (L. *Germania*, Germany), Ge; at. wt. 72.59; at. no. 32; m.p. 937.4°C; b.p. 2830°C; sp. gr. 5.323 (25°C); valence 2 and 4. Predicted by Mendeleev in 1871 as ekasilicon, and discovered by Winkler in 1886. The metal is found in *argyrodite*, a sulfide of germanium and silver; in *germanite*, which contains 8% of the element; in zinc ores; in coal; and in other minerals. The element is frequently obtained commercially from flue dusts of smelters processing zinc ores, and has been recovered from the by-products of combustion of certain coals. Its presence in coal insures a large reserve of the element in the years to come. Germanium can be separated from other metals by fractional distillation of its volatile tetrachloride. The tetrachloride may then be hydrolyzed to give GeO_2; then the dioxide can be reduced with hydrogen to give the metal. Recently developed zone-refining techniques permit the production of germanium of ultra-high purity. The

element is a gray-white metalloid, and in its pure state is crystalline and brittle, retaining its luster in air at room temperature. It is a very important semiconductor material. Doped with arsenic or gallium, it is used as a transistor element, which is rapidly displacing vacuum tubes in electronics. It is used also in the construction of rectifiers, photodiodes, etc. Transistors now provide the largest use for the element, but germanium is also finding many other applications including use as an alloying agent, as a phosphor in fluorescent lamps, and as a catalyst. The element is transparent to the infrared and is used in infrared spectroscopes and other optical equipment, including extremely sensitive infrared detectors. Its high index of refraction and dispersion has made germanium useful as a component of glasses used in wide angle camera lenses and microscope objectives. The field of organogermanium chemistry is becoming increasingly important. Certain germanium compounds have a low mammalian toxicity, but a marked activity against certain bacteria, which makes them of interest as chemotherapeutic agents. The cost of germanium is about 50 cents/gm. for 99.9+% purity in small lots.

GOLD (Sanskrit *Jval*; anglo-Saxon *gold*), Au (L. *aurum*, shining dawn); at. wt. 196.967; at. no. 79; m.p. 1063.0°C: b.p. 2966°C; sp. gr. 19.32 (20°C); valence 1 or 3. Known and highly valued from earliest times. Gold is found in nature as the free metal and in tellurides; it is very widely distributed and is almost always associated with quartz or pyrite. It occurs in veins and alluvial deposits, and is often separated from rocks and other minerals by sluicing or panning operations. The metal is also obtained from its ores by cyaniding, amalgamating, and smelting processes. Refining is also frequently done by electrolysis. Gold occurs in sea water to the extent of 0.1 to 2 mg/ton, depending on the location where the sample is taken. As yet no method has been found for recovering gold from sea water profitably. It is estimated that all the gold in the world, so far refined, could be placed in a single cube fifty feet on a side. Of all the elements, gold in its pure state is undoubtedly the most beautiful. It is metallic, having a yellow color when in a mass, but when finely divided it may be black, ruby, or purple. The Purple of Cassius is a delicate test for auric gold. It is the most malleable and ductile metal; one ounce of gold can be beaten out to 300 sq. ft. It is a soft metal and is usually alloyed to give it more strength. It is a good conductor of heat and electricity, and is unaffected by air and most reagents. It is used in coinage and is a standard for monetary systems in many countries. It is also extensively used for jewelry, decoration, dental work, and for plating. It has recently been used for coating certain space satellites, as it is a good reflector of infrared and is inert. Gold, like other precious metals, is measured in troy weight; when alloyed with other metals, the term *carat* is used to express the amount of gold present—24 carats being pure gold. For many years the value of gold was set by the United States at $20.67/troy oz; since 1934 this value has been fixed by law and Presidential Order at 35 dollars/troy oz. The commonest compounds are auric chloride ($AuCl_3$) and chlorauric acid ($HAuCl_4$), the latter being used in photography for toning the silver image. Gold has many isotopes; Au^{198}, with a half-life of 2.7 days is used for treating cancer and other diseases. A mixture of one part nitric acid with three of hydrochloric acid is called *aqua regia*, because it dissolves Gold, the King of Metals. Gold is available commercially with a purity of 99.999+%.

HAFNIUM (*Hafnia*, Latin name for Copenhagen), Hf; at. wt. 178.49; at. no. 72; m.p. 2150°C; b.p. 5400°C; sp. gr. 13.29; valence 4. Was suspected as being present in various minerals and concentrations many years prior to its discovery in 1923 by D. Coster and G. von Hevesey. On the basis of the Bohr theory, the new element was expected to be associated with zirconium, and it was finally identified in *zircon* from Norway, by means of x-ray spectroscopic analysis. It was named in honor of the city in which the discovery was made. Most zirconium minerals contain hafnium to the extent of 1 to 5%. It was originally separated from zirconium by repeated recrystallization of the double ammonium

or potassium fluorides by von Hevesey and Jantzen. Metallic hafnium was first prepared by van Arkel and deBoer by passing the vapor of the tetraiodide over a heated tungsten filament. Since the time hafnium was first separated from zirconium, many other methods of separation have been devised but only three have been found suitable for large-scale commercial production. The hot wire process, developed by van Arkel and deBoer, and the Kroll process are now commonly used to produce the metal. Hafnium has a brilliant silver luster. Its properties are considerably influenced by the impurities of zirconium present. Of all the elements, zirconium and hafnium are the two most difficult to separate. Their chemistry is almost identical; however the density of zirconium is about half that of hafnium. Very pure hafnium has been produced with zirconium being the major impurity. Because hafnium has a good absorption cross-section for thermal neutrons (almost 600 times that of zirconium), has excellent mechanical properties, and is extremely corrosion resistant, it is used for reactor control rods. Such rods are used in nuclear submarines, such as the *Nautilus*. Hafnium has been successfully alloyed with iron, titanium, niobium, tantalum, and other metals. Hafnium carbide is the most refractory binary composition known, and the nitride is the most refractory of all known metal nitrides (m.p. 3310°C). Hafnium is used in gas-filled and incandescent lamps, and is an efficient "getter" for scavenging oxygen and nitrogen. The price of the metal is in the broad range of 30 to 175 dollars/lb., depending on purity and quantity. The yearly production of hafnium in the U. S. is now in excess of 50,000 lb.

HELIUM (Gr. *helios*, the sun), He; at. wt. 4.0026; at. no. 2; m.p. below −272.2°C (26 atm.); b.p. −268.6°C; density 0.177 g/l; liquid density 7.62 lb./cu. ft. at. b.p.; valence 0. Evidence of the existence of helium was first obtained by Janssen during the solar eclipse of 1868 when he detected a new line in the solar spectrum; Lockyer and Frankland suggested the name *helium* for the new element; in 1895 Ramsay discovered helium in the uranium mineral *clevite*, and it was independently discovered in clevite by the Swedish chemists Cleve and Langlet about the same time. Except for hydrogen, helium is the most abundant element found throughout the universe. It has been detected spectroscopically in great abundance, especially in the hotter stars, and it is an important component in both the proton-proton reaction and the carbon cycle, which accounts for the energy of the sun and stars. The fusion of hydrogen into helium provides the energy of the hydrogen bomb. The helium content of the atmosphere is about 1 part in 200,000. Helium is chemically inert. While it is present in various radioactive minerals as a decay product, the bulk of the Free World's supply is obtained from wells in Texas, Oklahoma, and Kansas. The cost of helium fell from 2500 dollars/cu. ft. in 1915 to 1.5 cent/cu. ft. in 1940. The current price of 99.99% pure helium is about 13 cents/cu. ft. in small quantities. Helium has the lowest m.p. of any element and has found wide use in cryogenic research as its b.p. is close to absolute zero. Its use in the study of superconductivity is vital. Using liquid helium, Kurti and co-workers, and others, have succeeded in obtaining temperatures of a few microdegrees Kelvin, by the adiabatic demagnetization of copper nuclei, starting from about 0.01°K. Four isotopes of helium are known. Liquid helium exists in two forms: He I and He II, with a sharp transition point at 2.174°K (3.83 cm Hg). He I (above this temperature) is a normal liquid, but He II (below it) is unlike any other known substance. It expands on cooling; its conductivity for heat is enormous; and neither its heat conduction nor viscosity obey normal rules. It has other peculiar properties. Helium is the only liquid that cannot be solidified by lowering the temperature. It remains liquid down to absolute zero at ordinary pressures, but it can readily be solidified by increasing the pressure. Solid He^3 and He^4 are unusual in that both can readily be changed in volume by more than 30% by application of pressure. Helium is widely used as an inert gas shield for arc welding; as a lifting gas for balloons (being much safer than hydrogen); as a protective gas in growing silicon and germanium crystals, and in titanium and

zirconium production; as a cooling medium for nuclear reactors; and as a gas for supersonic wind tunnels. A mixture of 80% helium and 20% oxygen is used as an artificial atmosphere for divers and others working under pressure.

HOLMIUM (L. *Holmia*, for Stockholm), Ho; at. wt. 164.930; at. no. 67; m.p. 1461°C; b.p. 2600°C; sp. gr. 8.803; valence 3. The spectral absorption bands of holmium were noticed in 1878 by the Swiss chemists Delafontaine and Soret, who announced the existence of an "Element X." Cleve, of Sweden, later independently discovered the element while working on erbia earth. The element is named after Cleve's native city. Pure holmia, the yellow oxide, was prepared by Homberg in 1911. Holmium occurs in *gadolinite*, *monazite*, and in other rare-earth minerals. It is commercially obtained from *monazite*, occurring in that mineral to the extent of about 0.05%. It has been isolated in pure form only in recent years. It can be separated from other rare earths by ion-exchange techniques, and isolated by the reduction of its anhydrous fluoride with calcium metal. Pure holmium has a metallic to bright silver luster. It is relatively soft and malleable, and stable in dry air at room temperature, but rapidly oxidizes in moist air and at elevated temperatures. Few uses have yet been found for the element. The price of 99+% holmium metal is about 80 cents/gm.

HYDROGEN (Gr. *hydro*, water, and *genes*, forming), H; at. wt. 1.00797; at. no. 1; m.p. −259.14°C; b.p. −252.5°C; density 0.08988 g/l; sp. gr. liquid 0.070 (−252°C); valence 1. Hydrogen was prepared many years before it was recognized as a distinct substance by Cavendish in 1766. It was named by Lavoisier. Hydrogen is the most abundant of all elements in the universe, and it is thought that the heavier elements were, and still are being, built from hydrogen and helium. It has been estimated that hydrogen makes up more than 90% of all the atoms or three-quarters of the mass of the universe. It is found in the sun and most stars, and plays an important part in the proton-proton reaction and carbon-nitrogen cycle, which accounts for the energy of the sun and stars. Hydrogen is abundant in some planets, such as Jupiter; the core of this planet may consist of solid hydrogen, at least in part, and liquid hydrogen may be present elsewhere on the planet. On earth, hydrogen occurs chiefly in combination with oxygen in water, but it is also present in organic matter, such as living plants, petroleum, coal, etc. It is present as the free element in the atmosphere, but only to the extent of less than 1 part/million, by volume. It is the lightest of all gases, and combines with other elements, sometimes explosively, to form compounds. Great quantities of hydrogen are required commercially for the fixation of nitrogen from the air in the Haber ammonia process and for the hydrogenation of fats and oils. It is also used in large quantities in methanol production, in hydrodealkylation, hydrocracking, and hydrodesulfurization. It is also used as a rocket fuel, for welding, for production of hydrochloric acid, for the reduction of metallic ores, and for filling balloons. Production in the U. S. alone now amounts to hundreds of millions, of cubic feet per day. It is prepared by the action of steam on heated carbon, by decomposition of certain hydrocarbons with heat, by the electrolysis of water, or by the displacement from acids by certain metals. It is also produced by the action of sodium or potassium hydroxide on aluminum. Liquid hydrogen is important in cryogenics and in the study of superconductivity as its m.p. is only a few degrees above absolute zero. In 1932 Urey announced the preparation of a stable isotope, deuterium, with an atomic weight of 2. Two years later an unstable isotope, tritium, with an atomic weight of 3 was discovered. Tritium has a half-life of about 12.5 years. One part deuterium is found to about 6000 ordinary hydrogen atoms. Tritium atoms are also present but in much smaller proportion. Tritium is readily produced in nuclear reactors, and is used in the production of the hydrogen bomb. It is also used as a radioactive agent in making luminous paints. The current price of tritium, to authorized personnel, is about 2 dollars/curie; deuterium

gas is readily available, without permit, at about 1 dollar/liter. Heavy water, deuterium oxide, which is used as a moderator to slow down neutrons, is available without permit at a cost of 6 cents to 1 dollar/gm., depending on quantity and purity. Quite apart from isotopes, it has been shown that hydrogen gas under ordinary conditions is a mixture of two kinds of molecules, known as ortho- and para-hydrogen, which differ from one another by the spins of their electrons and nuclei.

INDIUM (from the brilliant indigo line in its spectrum), In; at. wt. 114.82; at. no. 49; m.p. 156.61°C; b.p. 2000 ± 10°C; sp. gr. 7.31 (20°C); valence 1,2(?), or 3. Discovered by Reich and Richter, who later isolated the metal. Indium is most frequently associated with zinc minerals, and it is from these that most commercial indium is now obtained; however, it is also found in iron, lead, and copper ores. Until 1924, a gram or so constituted the world's supply of this element in isolated form. It is now available in moderate quantities, but it must still be considered to be a rare element. It is probably about as abundant as silver. The present cost of indium is about $1.50 to $5.00/troy oz., depending on quantity and purity. It is available in ultrapure form. Indium is a very soft, silvery-white metal with a brilliant luster. The pure metal gives a high-pitched "cry" when bent. It wets glass, as does gallium. It has found application in making low-melting alloys; an alloy of 24% indium–76% gallium is liquid at room temperature. It is used in making bearing alloys, germanium transistors, rectifiers, thermistors, and photoconductors. It can be plated onto metal and evaporated onto glass forming a mirror as good as that made with silver, but with more resistance to atmospheric corrosion. There is evidence that indium is toxic and may be potentially hazardous to workers under certain conditions. Normal hygenic precautions should provide adequate protection.

IODINE (Gr. *iodes*, violet), I; at. wt. 126.9044; at. no. 53; m.p. 113.5°C; b.p. 184.35°; density of the gas 11.27 g/l; sp. gr. solid 4.93 (20°C); valence 1,3,5, or 7. Discovered by Courtois in 1811. Iodine, a halogen, occurs sparingly in the form of iodides in sea water from which it is assimilated by seaweeds, in Chilean saltpeter and nitrate-bearing earth, known as *caliche*, in brines from old sea deposits, and in brackish waters from oil and salt wells. Ultrapure iodine can be obtained from the reaction of potassium iodide with copper sulfate. Several other methods of isolating the element are known. Iodine is a grayish-black, lustrous solid, volatilizing at ordinary temperatures into a blue-violet gas with an irritating odor; it forms compounds with many elements, but is less active than the other halogens, which displace it from iodides. It dissolves readily in chloroform, carbon tetrachloride, or carbon disulfide to form beautiful purple solutions. It is only slightly soluble in water. Iodine compounds are important in organic chemistry and very useful in medicine. The artificial radioisotope I^{131}, with a half-life of 8 days, has been used in treating the thyroid gland. The most common compounds are the iodides of sodium and potassium (KI) and the iodates (KIO_3). Lack of iodine is the cause of goiter. The iodide and thyroxin, which contain iodine, are used internally in medicine, and a solution of KI and iodine in alcohol is used for external wounds. Potassium iodide finds use in photography. The deep blue color with starch solution is characteristic of the free element. Care should be taken in handling and using iodine as contact with the skin can cause lesions; iodine vapor is intensely irritating to the eyes and mucous membranes. The recommended maximum allowable concentration in air is 1 mg/cu. meter.

IRIDIUM (L. *iris*, rainbow), Ir; at. wt. 192.2; at. no. 77; m.p. 2410°C; b.p. 4527 ± 100°C; sp. gr. 22.42 (17°C); valence 3 or 4. Discovered in 1803 by Tennant in the residue left when crude platinum is dissolved by aqua regia. The name iridium is appropriate, for its salts are highly colored. Iridium, a metal of the platinum family, is white, similar to platinum, but with a slight yellowish cast. It is very hard and brittle, making it very hard to machine, form, or work. It is the most corrosion-resistant metal known, and was used

in making the standard meter in Paris, which is a 90% platinum–10% iridium alloy. Iridium occurs uncombined in nature with platinum and other metals of this family in alluvial deposits. It has found use in making crucibles and apparatus for use at high temperatures, and for electrical contacts. Its principal use is as a hardening agent for platinum. With osmium, it forms an alloy which is used for tipping pens and compass bearings. The specific gravity of iridium is only very slightly lower than that of osmium, which is generally credited as being the heaviest known element. The density of iridium and osmium, calculated from the space lattice, which with these elements may be more reliable than actual physical measurements, gives a density of 22.65 compared to 22.61 for osmium. At present, therefore, we know that either iridium or osmium is the densest known element, but the data do not allow selection between the two.

IRON (Anglo-Saxon, *iron*) Fe, (L. *ferrum*), at. wt. 55.847; at. no. 26; m.p. 1535°C; b.p. 3000°C; sp. gr. 7.874 (20°C); valence 2,3,4, or 6. The use of iron is prehistoric. Genesis mentions that Tubal-Cain, seven generations from Adam, was "an instructer of every artificer in brass and iron." Iron is a relatively abundant element in the universe. It is found in the sun and many types of stars in considerable quantity. Its nuclei are very stable. Iron is found native as a principal component of a class of meteorites known as *siderites*, and is a minor constituent of the other two classes. The core of the earth, 2150 miles in radius, is thought to be largely composed of iron with about 10% occluded hydrogen. The metal is the fourth most abundant element, by weight, making up the crust of the earth. The most common ore is *hematite* (Fe_2O_3), from which the metal is obtained by reduction with carbon. Iron is found in other widely distributed minerals, such as *magnetite* which is frequently seen as *black sands* along beaches and banks of streams. *Taconite* is becoming increasingly important as a commercial ore. Iron is a vital constituent of plant and animal life, and appears in hemoglobin. The pure metal is not often encountered in commerce, but is usually alloyed with carbon or other metals. The pure metal is very reactive chemically, and rapidly corrodes especially in moist air or at elevated temperatures. It has four allotropic forms, or ferrites, known as α, β, γ, and δ, with transition points at 770°, 928°, and 1530°C. The α form is magnetic but when transformed into the β form, the magnetism disappears although the lattice remains unchanged. The relations of these forms are peculiar. Pig iron is an alloy containing about 3% carbon with varying amounts of S, Si, Mn, and P. It is hard, brittle, fairly fusible, and is used to produce other alloys, including steel. Wrought iron contains only a few tenths of per cent of carbon, is tough, malleable, less fusible, and has usually a "fibrous" structure. Carbon steel is an alloy of iron with carbon, with small amounts of Mn, S, P, and Si. Alloy steels are carbon steels with other additives, such as nickel, chromium, vanadium, etc. Iron is the cheapest and most abundant, useful, and important of all metals.

KRYPTON (Gr. *kryptos*, hidden), Kr; at. wt. 83.80; at. no. 36; m.p. −156.6°C; b.p. −152.30 ± 0.10°C; density 3.733 g/l (0°C); valence 0. Discovered in 1898 by Ramsay and Travers in the residue left after liquid air had nearly boiled away. Krypton is present in the air to the extent of about 1 part per million. One of the rare gasses, it is characterized by its whitish color, similar to helium, when excited in a discharge tube, and by its brilliant green and orange spectral lines. Krypton has been used as a gas to fill small bright lamps, such as used by miners; to fill bactericidal lamp-starter tubes and special electron tubes; and is used in electron etching and ion engines. Krypton 85, one of the 19 known isotopes of krypton and an isotope which holds its radioactivity longer than other gases, is used to stabilize the starting potential of gas-filled electronic tubes by providing free electrons. While krypton is generally thought of as inert gas, the compound KrF_4 was recently reported as having been made. There is yet some question whether true compounds of inert gases exist. Krypton gas is readily available from commercial sources at about 3 cents per cc in small quantities.

LANTHANUM (Gr. *lanthanein*, to lie hidden), La; at. wt. 138.91; at. no. 57; m.p. 920°C; b.p. 3469°C; sp. gr. 5.98–6.186 (depending on crystal structure); valence 3. Mosander in 1839 extracted a new earth, lanthana, from cerium nitrate, and recognized the new element. It is found with other rare-earth minerals, including *cerite*, *monazite*, and *bastnaesite*. It occurs in monazite to the extent of 22%; in bastnaesite 26%. These two minerals are the most important commercial sources. Misch metal, used in making lighter flints, contains about 25% lanthanum. The metal was isolated in relatively pure form in 1923. Ion-exchange reactions have led to much easier isolation of the rare-earth elements and have resulted in much lower prices and abundance of the rare-earth metals. The metal can be produced commercially by reducing the anhydrous fluoride with calcium. Lanthanum is silvery white, malleable, ductile, and soft enough to be cut with a knife. Next to europium it is the most reactive of the rare earth metals, rapidly oxidizing when exposed to air. The metal lights in air at 440°C. It is a superconductor at 6°K. It exhibits three allotropic forms. Little is known of the toxicity of the rare earth metals; therefore they should be handled carefully until more data are forthcoming. Rare-earth compounds, containing lanthanum, are extensively used in carbon lighting applications, especially by the motion picture industry for studio lighting and projection. This application consumes about 25% of the rare earth compounds produced. The price of 99.9+% La_2O_3 is about 6 dollars/lb. The cost of the metal is about 110 dollars/lb.

LAWRENCIUM (Ernest O. Lawrence, inventor of the Cyclotron), Lr; at. no. 103; at. mass no. 257. The last member of the 5f transition elements (actinide series) was discovered March 1961 by A. Ghiorso, T. Sikkeland, A. E. Larsh, and R. M. Latimer. A three microgram californium target, consisting of a mixture of isotopes of mass number 249, 250, 251, and 252 was bombarded with either B^{10} or B^{11}. The electrically charged transmutation nuclei recoiled with an atmosphere of helium and were collected on a thin copper conveyor tape which was then moved to place collected atoms in front of a series of solid-state detectors. The isotope of element 103 produced in this way decayed by emitting an 8.6 Mev alpha particle with a half-life of 8 seconds. The chemical properties of lawrencium are not known, and it is doubtful if it will ever be possible to make chemical or physical studies with macroscopic amounts of this element. As with element 102, it has not been possible to obtain chemical identification of lawrencium; the discovery is based solely on nuclear evidence.

LEAD (Anglo-Saxon *lead*) Pb (L. *plumbum*); at. wt. 207.19; at. no. 82; m.p. 327.5; b.p. 1744°C; sp. gr. 11.35 (20°C); valence 2 or 4. Long known; mentioned in Exodus. The alchemists believed lead to be the oldest metal and associated it with the planet Saturn. Lead is obtained chiefly from galena (PbS) by a roasting process. It is a bluish-white metal of bright luster, very soft, highly malleable, is ductile and a poor conductor of electricity. It is very resistant to corrosion; lead pipes bearing the insignia of Roman emperors, used as drains from the baths, are still in service. It is used as containers for corrosive liquids, such as in sulfuric acid chambers, and it may be toughened by the addition of a small percentage of antimony or other metals. Its alloys include solder, type metal, and various antifriction metals. Great quantities of lead, both as the metal and as the dioxide, are used in storage batteries. Much metal also goes into cable covering, plumbing, ammunition, and in the manufacture of lead tetraethyl, used as an anti-knock compound in gasoline. The metal is very effective as a sound absorber, is used as a radiation shield around x-ray equipment and nuclear reactors, and is used to absorb vibration. White lead, the basic lead carbonate, sublimed white lead ($PbSO_4$), chrome yellow ($PbCrO_4$), red lead (Pb_3O_4) and other lead compounds are extensively used in paints. Lead oxide is used in producing fine "crystal glass" and "flint glass" of a high index of refraction for achromatic lenses. The nitrate and the acetate are soluble salts. Lead salts

are sometimes used in medicine, as antiseptics and astringents. Care must be used in both medicine and industry as lead is a cumulative poison.

LITHIUM (Gr. *lithos*, stone) Li; at. wt. 6.939; at. no. 3; m.p. 179°C; b.p. 1317°C; sp. gr. 0.534 (20°C); valence 1. Discovered by Arfvedson in 1817. Lithium is the lightest of all metals, with a density only about half that of water. It does not occur free in nature; combined it is found in small amounts in nearly all igneous rocks and in the waters of many mineral springs. *Lepidolite*, *spodumene*, *petalite*, and *amblygonite* are the more important minerals containing it. The metal is produced electrolytically from the fused chloride. Lithium is silvery in appearance much like Na and K, other members of the alkali metal series. It reacts with water, but not as vigorously as sodium. Lithium imparts a beautiful crimson color to a flame, but when the metal burns strongly the flame is a dazzling white. Since World War II, the production of lithium metal and its compounds has increased greatly. Because the metal has the highest specific heat of any solid element, it has found use in heat transfer applications; however it is corrosive and requires special handling. The metal has been used as an alloying agent, is of interest in synthesis of organic compounds, and it has nuclear applications. Lithium is used in special glasses and ceramics. The glass for the 200-inch telescope at Mt. Palomar contains lithium as a minor ingredient. Lithium chloride is one of the most hygroscopic materials known, and it, as well as lithium bromide, is used in air conditioning and industrial drying systems. Lithium stearate is used as an all-purpose and high-temperature lubricant. Other lithium compounds are used in dry cells and storage batteries. The metal is priced at about 10 dollars per lb.

LUTETIUM (*Lutetia*, ancient name for Paris—sometimes called *cassiopeium* by the Germans). Lu; at. wt. 174.97; at. no. 71; m.p. 1652°C; b.p. 3327°C; sp. gr. 9.872; valence 3. In 1907 Urbain described a process by which Marignac's ytterbium (1879) could be separated into the two elements, ytterbium (neoytterbium) and lutetium. These elements were identical with "aldebaranium" and "cassiopeium" independently discovered by von Welsbach about the same time. Charles James of the University of New Hampshire also independently prepared the very pure oxide, lutetia, at this time. The spelling of the element was changed from lutecium to lutetium very recently. Lutetium occurs in very small amounts in nearly all minerals containing yttrium, and is present in *monazite* to the extent of about 0.003%, which is a commercial source. The pure metal has been isolated only in recent years and is one of the most difficult to prepare. The metal is silvery white and relatively stable in air. While new techniques, including ion exchange reactions, have been developed to separate the various rare earth elements, lutetium is still the most costly of all naturally occurring rare earths, although it is slightly more abundant than thulium. It is now priced at about 10 dollars/gm. or 2100 dollars/lb. Lu^{176} which occurs naturally (2.5%) with Lu^{175} (97.5%), is radioactive with a half-life of about 7×10^{10} yrs. Virtually no commercial uses have been found yet for lutetium, as it is still one of the most costly natural elements.

MAGNESIUM (*Magnesia*, district in Thessaly), Mg; at. wt. 24.312; at. no. 12; m.p. 651°C; b.p. 1107°C; sp. gr. 1.738 (20°C); valence 2. Compounds of magnesium have long been known. Black recognized magnesium as an element in 1755. It was isolated by Davy in 1808, and prepared in coherent form by Bussy in 1831. Magnesium is the eighth most abundant element in the earth's crust. It does not occur uncombined, but is found in large deposits in the form of *magnesite*, *dolomite*, and other minerals. The metal is now principally obtained in the U.S. by electrolysis of fused magnesium chloride derived from brines, from wells and from sea water. Magnesium is a light, silvery white, and fairly tough metal. It tarnishes slightly in air, and finely divided magnesium readily ignites upon heating in air and burns with a dazzling white flame. It is used in flash-light photography, flares, and pyrotechnics, including incendiary bombs. It is one third lighter

than aluminum, and in alloys is essential for airplane and missile construction. The metal improves the mechanical, fabrication, and welding characteristics of aluminum, when used as an alloying agent. Magnesium is used in producing nodular graphite in cast iron, and is used as an additive to conventional propellants. It is also used as a reducing agent in the production of pure uranium and other metals from their salts. The oxide, chloride, sulfate, and citrate are used in medicine. Dead-burned magnesite is employed for refractory purposes, such as brick and liners in furnaces and converters. Organic magnesium compounds (Grignard's reaction) are important. Great care should be taken in handling magnesium, especially in the finely divided state, as serious fires can occur. Water should not be used on burning magnesium or on magnesium fires.

MANGANESE (L. *magnes*, magnet—from magnetic properties of pyrolusite; It. *manganese*, corrupt form of *magnesia*), Mn; at. wt. 54.9380; at. no. 25; m.p. 1244 ± 3°C; b.p. 2097°C; sp. gr. 7.21 to 7.44, depending on allotropic form; valence 1, 2, 3, 4, 6, or 7. Recognized by Scheele, Bergman, and others as an element and isolated by Gahn in 1774 by reduction of the dioxide with carbon. Manganese minerals are widely distributed; oxides, silicates, and carbonates are the most common. The recent discovery of large quantities of manganese nodules on the floor of the oceans appears promising as a new source of manganese. These nodules contain about 24% manganese together with many other elements in lesser abundance. Pyrolusite (MnO_2) and rhodochrosite ($MnCO_3$) are common ores. The metal is obtained by reduction of the oxide with sodium, magnesium, aluminum, or by electrolysis. It is gray-white, resembling iron, but is harder and very brittle. The metal is reactive chemically, and decomposes cold water slowly. Manganese is used to form many important alloys. In steel, manganese improves the rolling and forging qualities, strength, toughness, stiffness, wear resistance, hardness, and hardenability. With aluminum and antimony, especially with small amounts of copper, it forms highly ferromagnetic alloys. Manganese metal is ferromagnetic only after special treatment. The pure metal exists in four allotropic forms. The alpha form is stable at ordinary temperature; gamma manganese, which changes to alpha at ordinary temperatures, is said to be flexible, soft, easily cut, and capable of being bent. The dioxide (pyrolusite) is used as a depolarizer in dry cells, and is used to "decolorize" glass that is colored green by impurities of iron. Manganese by itself colors glass an amethyst color, and is responsible for the color of true amethyst. The dioxide is also used in the preparation of oxygen, chlorine, and in drying black paints. The permanganate is a powerful oxidizing agent and is used in quantitative analysis and in medicine.

MENDELEVIUM (Dmitri Mendeleev), Md; at. no. 101. Mendelevium, the ninth transuranium element of the actinide series to the discovered, was first identified by Ghiorso, Harvey, Choppin, Thompson, and Seaborg early in 1955 as a result of the bombardment of the isotope Es^{253} with helium ions in the Berkeley 60-inch cyclotron. The isotope produced was presumably Md^{256} which has a half-life of about 1.5 hours and apparently decays by electron capture to Fm^{256}, which in turn decays predominantly by spontaneous fission with a half-life of about 3 hours. This first identification was notable in that only of the order of one to three atoms per experiment was produced. The extreme sensitivity for detection depended on the fact that its chemical properties could be accurately predicted as eka-thulium. There was a high sensitivity for detection because of the spontaneous fission decay. The chemical properties have been investigated solely by the tracer technique and seem to indicate that the predominant oxidation state in aqueous solution is the (III) state. There seem to be no isotopes of sufficiently long half-life to make it possible to isolate this element in weighable quantity.

MERCURY (Planet *Mercury*), Hg (*hydrargyrum*, liquid silver); at. wt. 200.59; at. no. 80; m.p. −38.87°C; b.p. 356.58°C; sp. gr. 13.546 (20°C); valence 1 or 2. Known to

ancient Chinese and Hindus; found in Egyptian tombs of 1500 B.C. Mercury is the only common metal liquid at ordinary temperatures. It occurs free in nature, but the chief source is *cinnabar* (HgS). Spain and Italy produce about 50% of the world's supply of the metal. The commercial unit for handling mercury is the "flask," which weighs 76 lbs. The metal is obtained by heating cinnabar in a current of air and by condensing the vapor. It is a heavy, silvery white metal; a rather poor conductor of heat, as compared with other metals; and a fair conductor of electricity. The metal is widely used in laboratory work for making thermometers, barometers, diffusion pumps, and many other instruments. It is used in making mercury-vapor lamps and advertising signs, etc., and is used in mercury switches and other electrical apparatus. Other uses are for making pesticides, mercury cells for caustic-chlorine production, dental preparations, anti-fouling paint, batteries, and catalysts. The most important salts are mercuric chloride ($HgCl_2$, corrosive sublimate—a violent poison), mercurous chloride Hg_2Cl_2 (calomel—occasionally still used in medicine), mercury fulminate ($Hg(ONC)_2$, a detonator widely used in explosives), and mercuric sulfide (HgS, vermillion, a high-grade paint pigment). Organic mercury compounds are important. It is not generally appreciated that mercury is a virulent poison and is readily absorbed through the respiratory tract, the gastrointestinal tract, or through unbroken skin. It acts as a cumulative poison since only small amounts of the element can be eliminated at a time by the human organism. The maximum allowable concentration of mercury vapor in air has been set at 0.1 mg./cu. meter. Since mercury is a very volatile element, dangerous levels are readily attained in air. Air saturated with mercury vapor at 20°C contains a concentration which exceeds the toxic limit by more than 100 times. The danger increases at higher temperatures. *It is therefore important that mercury be handled with utmost care.* Containers of mercury should be securely covered and spillage should be avoided. If it is necessary to heat mercury or mercury compounds, it should be done in a well-ventilated hood.

MOLYBDENUM (Gr. *molybdos*, lead), Mo; at. wt. 95.94; at. no. 42; m.p. 2610°C; b.p. 5560°C; sp. gr. 10.22 (20°C); valence 2, 3, 4?, 5?, or 6. Before Scheele recognized molybdenite as a distinct ore of a new element in 1778, it was confused with graphite and lead ore. The metal was prepared in an impure form in 1782 by Hjelm. Molybdenum does not occur native, but is obtained from *molybdenite* (MoS_2) and from *wulfenite* ($PbMoO_4$). The metal is prepared from the powder made by the hydrogen reduction of purified molybdenum trioxide or ammonium molybdate. The metal is silvery white, very hard, but is softer and more ductile than tungsten. It has a high elastic modulus, and only tungsten and tantalum, of the more readily available metals, have higher melting points. It is a valuable alloying agent, as it contributes to the hardenability and toughness of quenched and tempered steels. It also improves the strength of steel at high temperatures. It is used in certain nickel-based alloys, such as the "Hastelloys," which are heat-resistant and corrosion-resistant to chemical solutions. Molybdenum oxidizes at elevated temperatures. The metal has found recent application as electrodes for electrically heated glass furnaces and forehearths. The metal is also used in nuclear energy applications and for missile and aircraft parts. Molybdenum wire is valuable for use as a filament material for metal evaporation work, and as a filament, grid, and screen material for electronic tubes. Molybdenum is an essential trace element in plant nutrition. Some lands are barren for lack of this element in the soil. Molybdenum sulfide is useful as a lubricant, especially at high temperatures where oils would decompose. Molybdenum powder is priced at about four dollars/lb., and bars rolled from arc-cast ingots cost about 15 dollars/lb.

NEODYMIUM (Gr. *neos*, new, and *didymos*, twin), Nd; at. wt. 144.24; at. no. 60; m.p. 1024°C; b.p. 3027°C; sp. gr. 6.80 and 7.004, depending on allotropic form; valence 3. In 1841 Mosander extracted from *cerite* a new rose-colored oxide, which he believed to contain a new element. He named the element *didymium*, as it was "an inseparable twin

brother of lanthanum." In 1885 von Welsbach separated didymium into two new elemental components, *neodymia* and *praseodymia*, by repeated fractionation of ammonium didymium nitrate. While the free metal is in *misch metal*, long known and used as a pyrophoric alloy for lighter flints, the element was not isolated in relatively pure form until 1925. Neodymium is present in misch metal to the extent of about 18%. It is present in the minerals *monazite* and *bastnaesite*, which are the principal sources of rare earth metals. The element may be obtained by separating neodymium salts from other rare earths by ion exchange techniques, and by reducing the salts by calcium metal, followed by volatilization of the calcium from the resulting neodymium-calcium alloy. Other separation techniques are possible. The metal has a bright silvery metallic luster. Neodymium is one of the more reactive rare-earth metals and quickly tarnishes in air, forming an oxide that spalls off and exposes metal to oxidation. The metal, therefore, should be kept under light mineral oil or sealed in a plastic material. Neodymium exists in two allotropic forms. Didymium, of which neodymium is a component, is used for coloring glass to make welder's goggles. By itself, neodymium colors glass a delicate lavender shade. Light transmitted through such glass shows unusually sharp absorption bands. This glass is useful in astronomical work to produce sharp bands by which other spectral lines may be calibrated, and it can be used as a laser material in place of ruby to produce coherent light. Neodymium salts are also used as a colorant for enamels. The price of the metal is about 50 cents/gm or 120 dollars/lb.

NEON (Gr. *neos*, new), Ne; at. wt. 20.183; at. no. 10; m.p. −248.67°C; b.p. −245.92°C (1 atm.); density of gas 0.89990 gm/l (1 atm. 0°C); density of liquid at b.p. 1.207 gm/cm^3; valence 0. Discovered by Ramsay and Travers in 1898. Neon is a rare gaseous element present in the atmosphere to the extent of 1 part in 65,000 of air. It is obtained by liquefaction of air and separated from the other gases by fractional distillation. It is a very inert element; however it is said to form a compound with fluorine. It is still questionable if true compounds of the rare gases exist, but evidence is mounting in favor of their existence. In a vacuum discharge tube, neon glows reddish orange. Of all the rare gases, the discharge of neon is the most intense at ordinary voltages and currents. Neon is used in making the common neon advertising signs, which accounts for its largest use. It is also used to make high-voltage indicators, lightning arrestors, wave meter tubes, and TV tubes. Liquid neon is now commercially available and is finding important application as an economical cryogenic refrigerant. It has over 40 times more refrigerating capacity per unit volume than liquid helium and more than three times that of liquid hydrogen. It is compact, inert, and is less expensive than helium when it meets refrigeration requirements. The gas costs about 1 dollar and 50 cents/liter.

NEPTUNIUM (planet *Neptune*), Np; at. no. 93; m.p. 640 ± 1°C; sp. gr. 18.0 to 20.45, depending on allotropic form; valence 3, 4, 5, and 6. Neptunium was the first of the synthetic transuranium elements of the actinide series to be discovered; the isotope Np^{239} was produced by McMillan and Abelson in 1940 at Berkeley, California, as the result of bombarding uranium with cyclotron-produced neutrons. The isotope Np^{237} (half-life of 2.2 ± 10^6 years) is currently obtained in gram quantities as a by-product from nuclear reactors in the production of plutonium. Trace quantities of the element are actually found in nature due to transmutation reactions in uranium ores produced by the neutrons which are present. Neptunium metal has a silvery appearance, is chemically reactive, and exists in at least three structural modifications: α-neptunium, orthorhombic, density—20.45 g/cm^3; β-neptunium (above 278°C), tetragonal, density (313°C)—19.36 g/cm^3; γ-neptunium (above 500°C) cubic, density (600°C) 18.0 g/cm^3. Neptunium has four ionic oxidation states in solution: Np^{+3} (pale purple), analogous to the rare earth ion Pm^{+3}, Np^{+4} (yellow green), NpO_2^+ (green blue), and NpO_2^{++} (pale pink). These latter oxygenated species are in contrast to the rare earths which exhibit only simple ions of the (II),

(III), and (IV) oxidation states in aqueous solution. The element forms tri- and tetrahalides such as NpF_3, NpF_4, $NpCl_4$, $NpBr_3$, NpI_3, and oxides of various compositions such as are found in the uranium-oxygen system, including Np_3O_8 and NpO_2. In 1962, the A.E.C. made Np^{237} available for sale to its licensees and for export. This isotope can be used as a component in neutron detection instruments. An initial allotment of 200 gms was offered at a price of 500 dollars/gm or 50 cents/mg plus handling and shipping charges.

NICKEL (Ger. *Nickel*, Satan or "Old Nick," and from *kupfernickel*, Old Nick's copper), Ni; at. wt. 58.71; at. no. 28; m.p. 1453°C; b.p. 2732°C; sp. gr. 8.902 (25°C); valence 0, 1, 2, 3. Discovered by Cronstedt in 1751 in kupfernickel (*niccolite*). Nickel is found as a constituent in most meteorites and often serves as one of the criteria for distinguishing a meteorite from other minerals. Iron meteorites, or *siderites*, may contain iron alloyed with from 5% to nearly 20% nickel. Nickel is obtained commercially from *pentlandite* and *pyrrhotite* of the Sudbury region of Ontario. This district produces about 70% of the nickel for the free world. Small deposits are found in Norway, New Caledonia, Cuba, Japan, and elsewhere. Nickel is silvery-white and takes on a high polish. It is hard, malleable, ductile, somewhat ferromagnetic, and a fair conductor of heat and electricity. It belongs to the iron-cobalt group of metals and is chiefly valuable for the alloys it forms. It is extensively used for making stainless steel and other corrosion-resistant alloys, such as Invar, Monel, Inconel, and the Hastelloys. It is also used in coinage, in making nickel steel for armor plate and burglar-proof vaults, and is a component in Nichrome, Permalloy, and Constantan. Nickel added to glass gives a green color. Nickel plating is often used to provide a protective coating for other metals, and finely divided nickel is a catalyst for hydrogenating vegetable oils. It is also used in ceramics, in the manufacture of Alnico magnets, and in the Edison storage battery. The sulfate and the oxides are important compounds.

NIOBIUM (*Niobe*, daughter of Tantalus), Nb; or **COLUMBIUM** (*Columbia*, name for America); Cb; at. wt. 92.906; at. no. 41; m.p. 2468 ± 10°C; b.p. 4927°C; sp. gr. 8.57 (20°C); valence 2, 3, 4?, 5. Discovered in 1801 by Hatchett in an ore sent to England more than a century before by John Winthrop the Younger, first governor of Connecticut. The metal was first prepared in 1864 by Blomstrand, who reduced the chloride by heating it in a hydrogen atmosphere. The name "niobium" was adopted by the International Union of Pure and Applied Chemistry in 1950 after 100 years of controversy. Many leading chemical societies and government organizations refer to it by this name. Most metallurgists, leading metals societies, and all but one of the leading U.S. commercial producers, however, still refer to the metal as "columbium." The element is found in *columbite-tantalite*, *pyrochlore*, and *euxenite*. Extensive ore reserves are found in Canada, Norway, Africa, and the U.S. The metal can be isolated from tantalum, and prepared in several ways. It is a shiny, white, soft, and ductile metal, and takes on a bluish cast when exposed to air at room temperatures for a long time. The metal starts to oxidize in air at 200°C, and when processed at even moderate temperatures must be placed in a protective atmosphere. It is used as an alloying agent in carbon and alloy steels as well as with nonferrous metals. These alloys have improved strength and other desirable properties. The metal has a low capture cross-section for thermal neutrons. It is used in arc-welding rods for stabilized grades of stainless steel. The element has superconductive properties; a superconductive magnet has been made with Nb-Zr wire, which retains its superconductivity in strong magnetic fields. This type of application is said to offer hope of direct large-scale generation of electric power. In small quantities, columbium metal costs from 50 cents to 1 dollar/gm.

NITROGEN (L. *nitrum*, Gr. *nitron*, native soda; genes, *forming*), N; at. wt. 14.0067; at. no. 7; m.p. −209.86°C; b.p. −195.8°C; density 1.2506 g/l; sp. gr. liquid 0.808

(−195.8°C), solid 1.026 (−252°C); valence 3 or 5. Discovered by Daniel Rutherford in 1772, but Scheele, Cavendish, Priestley, and others about the same time studied "burnt or dephlogisticated air," as air without oxygen was then called. Nitrogen makes up 78% of the air, by volume. The estimated amount of this element in the atmosphere is more than 4000 billion tons. From this inexhaustible source it can be obtained by liquefaction and fractional distillation. The element is so inert that Lavoisier named it *azote*, meaning without life, yet its compounds are so active as to be most important in foods, poisons, fertilizers, and explosives. Nitrogen can be also easily prepared by heating a water solution of ammonium nitrite. Nitrogen, as a gas, is colorless, odorless, and a generally inert element. As a liquid it is also colorless and odorless, and is similar in appearance to water. When nitrogen is heated, it combines directly with magnesium, lithium, or calcium; when mixed with oxygen and subjected to electric sparks, it forms first nitric oxide (NO) and then the dioxide (NO_2); when heated under pressure with a catalyst with hydrogen, ammonia is formed (Haber process). The ammonia thus formed is of the utmost importance as it is used in fertilizers, and it can be oxidized to nitric acid (Ostwald process). The ammonia industry is the largest consumer of nitrogen. Large amounts of the gas are also used by the electronics industry, which uses the gas as a blanketing medium during production of such components as transistors, diodes, etc. The drug industry also uses large quantities. Nitrogen holds promise as a refrigerant both for the immersion freezing of food products and for transportation of foods. Liquid nitrogen is also used in missile work as a purge for components, insulators for space chambers, etc., and by the oil industry to build up great pressures in wells to force crude oil upward. Sodium and potassium nitrates are formed by the decomposition of organic matter with compounds of the metals present. In certain dry areas of the world these saltpeters are found in quantity. Ammonia, nitric acid, the nitrates, the five oxides (N_2O, NO, N_2O_3, NO_2, and N_2O_5), TNT, the cyanides, etc., are but a few of the important compounds. Nitrogen gas prices vary from 2 cents to $2.75 per 100 cu. ft., depending on purity, etc. Production of nitrogen in the U.S. is about 40 billion cubic feet per year or more.

NOBELIUM (See Element No. 102)

OSMIUM (Gr. *osme*, a smell) Os; at. wt. 190.2; at. no. 76; m.p. 3000 ± 10°C; b.p. 5000°C; sp. gr. 22.57; valence 2, 3, 4, or 8. Discovered in 1803 by Tennant in the residue left when crude platinum is dissolved by aqua regia. Osmium occurs in *iridosime* and in platinum-bearing river sands of the Urals, North America, and South America. It is also found in the nickel-bearing ores of the Sudbury, Ontario region along with other platinum metals. While the quantity of platinum metals in these ores is very small, the large tonnages of nickel ores processed make commercial recovery possible. The metal is lustrous, bluish-white, extremely hard, and brittle even at high temperatures. It has the highest melting point and lowest vapor pressure of the platinum group. The metal is very difficult to fabricate, but the powder can be sintered in a hydrogen atmosphere at a temperature of 2000°C. The solid metal is not affected by air at room temperature, but the powered or spongy metal slowly gives off osmium tetroxide, which is a powerful oxidizing agent and has a strong smell. The tetroxide is highly toxic, and boils at 130°C (760 mm). Concentrations in air as low as 10^{-7} gm/cu meter can cause lung congestion, skin damage, or eye damage. The tetroxide has been used to detect fingerprints and to stain fatty tissue for microscopic slides. The metal is almost entirely used to produce very hard alloys, with other metals of the platinum group, for fountain pen tips, instrument pivots, phonograph needles, and electrical contacts. The price of 99% pure osmium powder—the form usually supplied commercially—is about 3 dollars to 8 dollars/gm, depending on quantity and supplier. The measured density of iridium and osmium seem to indicate that osmium is slightly more dense than iridium, and osmium has generally been credited with being the heaviest known element. Calculations of the density from the space lattice, which may be

more reliable for these elements than actual measurements, however, give a density of 22.65 for iridium compared to 22.61 for osmium. At present, therefore, we know either iridium or osmium is the heaviest element, but the data do not allow selection between the two.

OXYGEN (Gr. *oxys*, sharp, acid, and *genes*, forming; acid former), O; at. wt. 15.9994; at. no. 8; m.p. −218.4°C; b.p. −183.0°C; density 1.429 g/l (0°C); sp. gr. liquid 1.14 (−182.96°C); valence 2. For many centuries, workers from time-to-time realized air was composed of more than one component. The behavior of oxygen and nitrogen as components of air, led to the advancement of the phlogiston theory of combustion, which captured the minds of chemists for a century. Oxygen was prepared by several workers, including Bayen and Borch, but they did not know how to collect it, did not study its properties, nor did they recognize it as an elementary substance. Priestley is generally credited with its discovery, although Scheele also discovered it independently. Oxygen is the third most abundant element found in the universe, and it plays a part in the carbon-nitrogen cycle—one process thought to give the sun and stars their energy. Oxygen, as a gaseous element, forms 21% of the atmosphere by volume from which it can be obtained by liquefaction and fractional distillation. The element and its compounds make up 49.2%, by weight, of the earth's crust. About two thirds of the human body, and nine tenths of water is oxygen. In the laboratory it can be prepared by the electrolysis of water or by heating potassium chlorate with manganese dioxide as a catalyst. The gas is colorless, odorless, and tasteless. The liquid and solid forms are a pale blue color and are magnetic, but much less so than iron. Ozone (O_3), a highly active allotropic form of oxygen, is formed by the action of an electrical discharge or ultra-violet light on oxygen. Ozone's presence in the atmosphere (amounting to the equivalent of a layer 3 mm thick at ordinary pressures and temperatures) is of vital importance in preventing ultraviolet rays from the sun from reaching the earth's surface and destroying life on earth. Oxygen is very reactive and capable of combining with most elements. It is a component of hundreds of thousands of organic compounds. It is essential for respiration of all plants and animals and for practically all combustion. In hospitals it is frequently used to aid respiration of patients. Its atomic weight was used as a standard of comparison for each of the other elements until 1961 when the International Union of Pure and Applied Chemistry adopted carbon 12 as the new basis. Oxygen has six isotopes. Oxygen 18 occurs naturally, is stable, and is available commercially. Water (H_2O^{18} with 1.5% O^{18}) is also available. Commercial oxygen consumption in the U.S. is estimated at more than 140 billion cubic feet/year, and the demand is expected to double in the next few years. Oxygen enrichment for steel blast furnaces is the greatest user of the gas. Large quantities are also used in making synthesis gas for ammonia and methanol, ethylene oxide, and for oxy-acetylene welding. Air separation plants produce about 99% of the gas; electrolysis plants about 1%. The gas costs about 2.5 cents/cubic foot in relatively small quantities.

PALLADIUM (named after the asteroid *Pallas*, discovered about the same time; Gr. *Pallas*, goddess of wisdom), Pd; at. wt. 106.4; at. no. 46; m.p. 1552°C; b.p. 2927°C; sp. gr. 12.02 (20°C); valence 2, 3, or 4. Discovered in 1803 by Wollaston. Palladium is found along with platinum and other metals of the platinum group in placer deposits of the U.S.S.R., South and North America, Abyssinia, and Australia. It is also found associated with the nickel-copper deposits of South Africa and Ontario. Its separation from the platinum metals depends upon the type of ore in which it is found. It is a steel-white metal, does not tarnish in air, and is the least dense and lowest melting of the platinum group of metals. When annealed, it is soft and ductile; cold working greatly increases its strength and hardness. Palladium is attacked by nitric and sulfuric acid. At room temperatures the metal has the unusual property of absorbing up to 900 times its own volume of hydrogen, possibly forming Pd_2H. It is not yet clear if this is a true compound. Hydrogen readily diffuses through heated palladium and this provides a means of purifying the gas. Finely

divided palladium is a good catalyst and is used for hydrogenation and dehydrogenation reactions. It is alloyed and used in jewelry trades. White gold is an alloy of gold decolorized by the addition of palladium. Like gold, palladium can be beaten into leaf as thin as 1/250,000 inch. The metal is used in dentistry, watchmaking, and in making surgical instruments and electrical contacts. The metal sells for about 25 dollars/troy ounce.

PHOSPHORUS (Gr. *phosphoros*, light-bearing; ancient name for the planet Venus when appearing before sunrise), P; at. wt. 30.9738; at. no. 15; m.p. (white) 44.1°C; b.p. (white) 280°C; sp. gr. (white) 1.82, (red) 2.20, (black) 2.25 to 2.69; valence 3 or 5. Discovered in 1669 by Brand, who prepared it from urine. Phosphorus exists in three allotropic forms: white (or yellow), red, and black (or violet). Never found free in nature, it is widely distributed in combination with minerals. *Phosphate* rock, which contains the mineral *apatite*—an impure tri-calcium phosphate, is an important source of the element. Large deposits are found in the U.S.S.R., in Morocco, and in Florida, Tennessee, Utah, Idaho, and elsewhere. Phosphorus is an essential ingredient of all cell protoplasm, nervous tissue, and bones. Ordinary phosphorus is a waxy white solid; when pure it is colorless and transparent. It is insoluble in water, but soluble in carbon disulfide. It takes fire spontaneously in air, burning to the pentoxide. It is very poisonous—50 mg constituting an approximate fatal dose. The maximum recommended allowable concentration in air is 0.1 mg/cubic meter. White phosphorus should be kept under water as it is dangerously reactive in air, and it should be handled with forceps, as contact with the skin may cause severe burns. When exposed to sunlight or when heated in its own vapor to 250°C, it is converted to the red variety, which does not phosphoresce in air as does the white variety. This form does not ignite spontaneously and it is not as dangerous as white phosphorous. It should, however, be handled with care as it does convert to the white form at some temperatures and it emits highly toxic fumes of the oxides of phosphorus when heated. The red modification is fairly stable, sublimes with a vapor pressure of 1 atm. at 417°C, and is used in the manufacture of safety matches, pyrotechnics, pesticides, incendiary shells, smoke bombs, tracer bullets, etc. White phosphorus may be made by several methods. By one process, tri-calcium phosphate, the essential ingredient of phosphate rock, is heated in the presence of carbon and silica in an electric furnace or fuel-fired blast furnace. Elementary phosphorus is liberated as vapor and may be collected under water. If desired, the phosphorus vapor and carbon monoxide produced by the reaction can be oxidized at once in the presence of moisture or water to produce phosphoric acid—an important compound in making super-phosphate fertilizers. In recent years, concentrated phosphoric acids, which may contain as much as 70 to 75% P_2O_5 content, have become of great importance to agriculture and farm production. World-wide demand for fertilizers has caused record phosphate production in recent years. Phosphates are used in the production of special glasses, such as those used for sodium lamps. Bone-ash, calcium phosphate, is also used to produce fine china-ware and to produce mono-calcium phosphate used in baking powder. Phosphorus is also important in the production of steels, phosphor bronze, and many other products. Tri-sodium phosphate is important as a cleaning agent, as a water-softener, and for preventing boiler scale and corrosion of pipes and boiler tubes. Organic compounds of phosphorus are important.

PLATINUM (Sp. *platina*, silver), Pt; at. wt. 195.09; at. no. 78; m.p. 1769°C; b.p. 3827 ± 100°C; sp. gr. 21.45 (20°C); valence 1?, 2, 3, or 4. Discovered in South America by Ulloa in 1735 and by Wood in 1741. The metal was used by pre-Colombian Indians. Platinum occurs native, accompanied by small quantities of iridium, osmium, palladium, ruthenium, and rhodium, all belonging to the same group of metals. These are found in the alluvial deposits of the Ural mountains, of Colombia, and of certain western American states. *Sperrylite* ($PtAs_2$) occurring with the nickel-bearing deposits of Sudbury, Ontario, is the source of a considerable amount of the metal. The large production of nickel offsets

the fact that there is only one part of the platinum metals in two million parts of ore. Platinum is a beautiful silvery-white metal, when pure, and is malleable and ductile. It has a coefficient of expansion almost equal to that of soda-lime-silica glass, and is therefore used to make sealed electrodes in glass systems. The metal does not oxidize in air at any temperature, but is corroded by halogens, cyanides, sulfur, and caustic alkalis. It is insoluble in hydrochloric and nitric acid, but dissolves when they are mixed as *aqua regia*, forming chloroplatinic acid (H_2PtCl_6), an important compound. The metal is extensively used in jewlery, in wire and vessels for laboratory use, and in many valuable instruments, including thermocouple elements. It is also used for electrical contacts, corrosion-resistant apparatus, and in dentistry. Platinum-cobalt alloys have magnetic properties. One such alloy made of 76.7% Pt and 23.3% Co, by weight, is an extremely powerful magnet that offers a B-H (max) almost twice that of Alnico V. Platinum resistance wires are used for constructing high-temperature electric furnaces. The metal is used for coating missile nose cones, jet engine fuel nozzles, etc., which must perform reliably for long periods of time at high temperatures. The metal, like palladium, absorbs large volumes of hydrogen, retaining it at ordinary temperatures but giving it up at red heat. In the finely divided state platinum is an excellent catalyst, having long been used in the contact process for sulfuric acid, of which it does not now have a monopoly. Fine platinum wire will glow red hot when placed in the vapor of methyl alcohol. It acts here as a catalyst, converting the alcohol to formaldehyde. This phenomenon has been used commercially to produce cigarette lighters and hand warmers. Hydrogen and oxygen explode in the presence of platinum. The price of platinum has varied widely; more than a century ago it was used to adulterate gold. It was nearly eight times as valuable as gold in 1920; the present price is about 135 dollars/troy ounce.

PLUTONIUM (Planet *Pluto*), Pu; at. no. 94; at. mass (~239); sp. gr. (α modification) 19.84 (25°C); m.p. 639.5 ± 2°C; b.p. 3235 ± 19°C; valence 3, 4, 5, or 6. Plutonium was the second transuranium element of the actinide series to be discovered. The isotope Pu^{238} was produced in 1940 by Seaborg, McMillan, Kennedy, and Wahl by deuteron bombardment of uranium in the 60-inch cyclotron at Berkeley, California. Plutonium also exists in trace quantities in naturally occurring uranium ores. It is formed in much the same manner as neptunium, by irradiation of natural uranium with the neutrons which are present. By far of greatest importance is the isotope Pu^{239}, with a half-life of 24,360 years, produced in extensive quantities in nuclear reactors from natural uranium:

$$U^{238}\ (n,\gamma)\ U^{239} \xrightarrow{\beta^-} Np^{239} \xrightarrow{\beta^-} Pu^{239}$$

Fifteen isotopes of plutonium are known. Plutonium has assumed the position of dominant importance among the transuranium elements because of its successful use as an explosive ingredient in nuclear weapons and the place which it holds as a key material in the development of industrial use of nuclear power. One pound is equivalent to about ten million kilowatt hours of heat energy. Its importance depends on the nuclear property of being readily fissionable with neutrons and its availability in quantity. As with neptunium and uranium, plutonium metal can be prepared by reduction of the trifluoride with alkaline-earth metals. The metal has a silvery appearance and takes on a yellow tarnish when slightly oxidized. It is chemically reactive. A relatively large piece of plutonium is warm to the touch because of the energy given off in alpha decay. Larger pieces will produce enough heat to boil water. The metal readily dissolves in concentrated hydrochloric acid, hydroiodic acid, or perchloric acid with formation of the Pu^{+3} ion. The metal exhibits six allotropic modifications having various crystalline structures. The densities of these vary from 15.92 to 19.84. Plutonium also exhibits four ionic valence states in aqueous solutions: Pu^{+3} (blue lavender), Pu^{+4} (yellow brown), PuO_2^{+} (pink?) and PuO_2^{+2} (pink orange). The ion PuO_2^{+} is unstable in aqueous solutions, disproportionating into Pu^{+4} and PuO_2^{+2}; the

Pu^{+4} thus formed, however, oxidizes the PuO_2^+ into PuO_2^{+2}, itself being reduced to Pu^{+3}, giving finally Pu^{+3} and PuO_2^{+2}. Plutonium forms binary compounds with oxygen: PuO, PuO_2, and intermediate oxides of variable composition; with the halides: PuF_3, PuF_4, $PuCl_3$, $PuBr_3$, PuI_3; with carbon, nitrogen, and silicon: PuC, PuN, $PuSi_2$. Oxyhalides are also well known: PuOCl, PuOBr, PuOI. Because of the high rate of emission of alpha particles and the fact that the element is specifically absorbed by bone marrow, plutonium, as well as all of the other transuranium elements except neptunium, are radiological poisons and must be handled with special equipment and precautions. The body burden, or the amount that can be maintained indefinitely in an adult without producing significant body injury, for Pu^{239} is now recommended to be 0.008 microcuries, which is equivalent to 0.0005 micrograms. When quantities in excess of 300 g are handled, criticality must be considered. Plutonium standard units, consisting of about 1/2 g of plutonium metal sealed in a glass ampoule under a reduced argon atmosphere, are supplied by the National Bureau of Standards to A.E.C. licensees at about 34 dollars.

POLONIUM (Poland, native country of Mme. Curie), Po; at. mass (~210); at. no. 84; m.p. 254°C; b.p. 962°C; sp. gr. (alpha modification) 9.32; valence 2, 4 or 6. First element discovered by Mme. Curie, in 1898, while seeking the cause of radioactivity of pitchblende from Joachimsthal, Bohemia. The electroscope showed it separating with bismuth. Polonium is also called Radium F. Polonium is a very rare natural element. Uranium ores contain only about 100 micrograms of the element per ton. Its abundance is only about 0.2% of that of radium. In 1934 it was found that when natural bismuth (Bi^{209}) was bombarded by neutrons, Bi^{210}, the parent of polonium, was obtained. Milligram amounts of polonium may now be prepared this way, by using the high neutron fluxes of nuclear reactors. Polonium-210 is a low-melting, fairly volatile metal, 50% of which is vaporized in air in 45 hours at 55°C. It is an alpha-emitter with a half-life of 138.39 days. A milligram emits as many alpha particles as 5 grams of radium. The energy released by its decay is so large (27.5 calories per curie per day) that a capsule containing about half a gram reaches a temperature above 500°C. The capsule also presents a contact gamma-ray dose rate of 1.2 roentgens per hour. A few curies of polonium exhibit a blue glow, caused by excitation of the surrounding gas. Because almost all alpha radiation is stopped within the solid source and its container, giving up its energy, polonium has attracted attention for uses as a light-weight heat source for thermoelectric power in space satellites. Twenty-seven isotopes of polonium are known, with atomic masses ranging from 192 to 218. Polonuim-210 is the most readily available. Isotopes of mass 209 (half-life of 103 yrs.) and mass 208 (half-life of 2.9 yrs.) can be prepared by alpha, proton, or deuteron bombardment of lead or bismuth in a cyclotron, but these are expensive to produce. Metallic polonium has been prepared from polonium hydroxide and some other polonium compounds in the presence of concentrated aqueous or anhydrous liquid ammonia. Two allotropic modifications are known to exist. Polonium is readily dissolved in dilute acids, but is only slightly soluble in alkalis. Polonium salts of organic acids char rapidly; halide ammines are reduced to the metal. Polonium can be mixed or alloyed with beryllium to provide a source of neutrons. It has been used in devices for eliminating static charges in textile mills, etc; however, beta sources are more commonly used and are less dangerous. It is also used on brushes for removing dust from photographic films. The polonium for these is carefully sealed and controlled, minimizing hazards to the user. Polonium-210 is very dangerous to handle in even milligram or microgram amounts and special equipment and strict control is necessary. Damage arises from the complete absorption of the energy of the alpha particle into tissue. The maximum permissible body-burden for ingested polonium is only 0.03 microcuries, which represents a particle weighing only 6.8×10^{-12} grams. Weight-for-weight it is about 2.5×10^{11} times as toxic as hydrocyanic acid. The maximum allowable concentration for soluble polonium compounds, in air is about 2×10^{-11} microcuries/cc. Polonium

chloride or nitrate is available commercially with an A.E.C. permit at a cost of about 6 dollars/millicurie, plus service charges.

POTASSIUM (English, *potash*—pot ashes; L. *kalium;* Arab. *qali*, alkali), K; at. wt. 39.102; at. no. 19; m.p. 63.65°C; b.p. 774°C; sp. gr. 0.862 (20°C); valence 1. Discovered in 1807 by Davy, who obtained it from caustic potash (KOH); this was the first metal isolated by electrolysis. The metal is the seventh most abundant and makes up about 2.4% by weight of the earth's crust. Most potassium minerals are insoluble and the metal is obtained from them only with great difficulty. Certain minerals, however, such as *sylvite*, *carnallite*, *langbeinite*, and *polyhalite* are found in ancient lake and sea beds and form rather extensive deposits from which potassium and its salts can readily be obtained. Potash is mined in Germany, New Mexico, California, Utah, and elsewhere. Large deposits of potash, found at a depth of some 3000 ft. in Saskatchewan, promise to be important in coming years. Potassium is also found in the ocean, but is present only in relatively small amounts, compared to sodium. The greatest demand for potash has been in its use for fertilizers. Potassium is never found free in nature, but is obtained by electrolysis of the hydroxide, much in the same manner as prepared by Davy. It is one of the most reactive and electropositive of metals; except for lithium, it is the lightest known metal. It is soft, easily cut with a knife, and is silvery in appearance immediately after a fresh surface is exposed. It rapidly oxidizes in air and must be preserved in a mineral oil, such as kerosene. As with other metals of the alkali group, it decomposes in water with the evolution of hydrogen. It catches fire spontaneously on water. Potassium and its salts impart a violet color to flames. Nine isotopes of potassium are known. Ordinary potassium is composed of $0.0119\%K^{40}$, a radioactive isotope with a half-life of 1.4×10^9 yrs. The radioactivity is only about 1/1000 that of uranium, and therefore presents no appreciable hazard. An alloy of sodium and potassium (NaK) is used as a heat-transfer medium. Many potassium salts are of utmost importance. These include the hydroxide, nitrate, carbonate, chloride, chlorate, bromide, iodide, cyanide, sulfate, chromate, and dichromate. Metallic potassium is available commercially for about 2 dollars/lb. in quantity.

PRASEODYMIUM (Gr. *prasios*, green, and *didymos*, twin), Pr; at. wt. 140.907; at. no. 59; m.p. 935°C; b.p. 3127°C; sp. gr. (α) 6.782, (β) 6.64; valence 3 or 4. In 1841 Mosander extracted the rare earth *didymia* from *lanthana*; in 1879 Lecoq de Boisbaudran isolated a new earth, *samaria*, from didymia obtained from the mineral *samarskite*. Six years later, in 1885, von Welsbach separated didymia into two other earths, *praseodymia* and *neodymia*, which gave salts of different colors. As with other rare-earths, compounds of these elements in solution have distinctive sharp spectral absorption bands or lines, some of which are only a few Ångstroms wide. The element occurs along with other rare-earth elements in a variety of minerals. *Monazite* and *bastnaesite* are the two principal commercial sources of the rare-earth metals. Ion-exchange techniques have led to much easier isolation of the rare earths and the cost has dropped greatly in the past few years. Praseodymium can be prepared by several methods, such as by calcium reduction of the anhydrous chloride or fluoride. Misch metal, used in making cigarette lighters, contains about 5% praseodymium metal. Praseodymium is soft, silvery, malleable, and ductile. It was prepared in relatively pure form in 1931. It is somewhat more resistant to corrosion in air than europium, lanthanum, cerium or neodymium, but it does develop a green oxide coating that spalls off, when exposed to air. As with other rare earth metals is should be kept under a light mineral oil, or sealed in plastic. Along with other rare earths, it is widely used as a core material for carbon arcs used by the motion picture industry for studio lighting and projection. Salts of praseodymium are used to color glasses and enamels; when mixed with certain other materials, praseodymium produces an intense and unusually clean yellow color in glass. Didymium glass, of which praseodymium is a compon-

ent, is a colorant for welder's goggles. The metal (99+% pure) is priced at about 60 cents per gram or 13 dollars/lb.

PROMETHIUM (*Prometheus*, who, according to mythology, stole fire from heaven), Pm; at. no. 61; m.p. 1035°C; b.p. 2730°C; sp. gr.....; valence 3. In 1902 Branner predicted the existence of an element between neodymium and samarium, and this was confirmed by Moseley in 1914. In 1941, workers at Ohio State University irradiated neodymium and praseodymium with neutrons, deuterons, and alpha particles, resp., and produced several new radioactivities, which most likely were those of Element 61. Wu and Segré, and Bethe, in 1942, confirmed the formation; however chemical proof of the production of Element 61 was lacking because of the difficulty in separating the rare earths from each other at that time. In 1945, Marinsky, Glendenin, and Coryell made the first chemical identification by use of ion-exchange chromatography. Their work was done by fission of uranium and by neutron bombardment of neodymium. Searches for the element in nature have been fruitless, and it now appears that promethium is completely missing from the earth's crust. Fourteen isotopes of promethium, with atomic masses from 141 to 154, are now known. Promethium–147, with a half-life of 2.64 yrs., is the most generally useful. Promethium has a specific activity of about 1 curie per milligram. It is a soft beta emitter; although no gamma rays are emitted, x-radiation can be generated when beta particles impinge on elements of a high atomic number, and care must be taken in handling it. Ion-exchange methods led to the preparation of about 10g of promethium from atomic reactor fuel processing wastes in early 1963. The element has applications as a beta source for thickness gages, and it can be absorbed by a phosphor to produce light. Light produced in this manner can be used for signs or signals that require dependable operation; it can be used as a nuclear-powered battery by capturing light in photocells which convert it into electric current. Such a battery, using Pm^{147}, would have a useful life of about 5 yrs. Promethium shows promise as a portable x-ray unit, and it may become useful as a heat source to provide auxiliary power for space probes and satellites. Promethium–147 is available to A.E.C. licensees at a cost of about $3.25 per curie in small quantities.

PROTACTINIUM (Gr. *protos*, first), Pa; at. wt. (~231); at. no. 91; m.p. ~1230? b.p. . . .; sp. gr. 15.37 (calc.); valence 4 or 5. Soddy, Russell, and Fajans independently predicted the existence of eka-tantalum (also known as Uranium X_2), a new member of the uranium series which would occupy the vacant space just below tantalum in the periodic table. The element was discovered in 1917 independently by Hahn and Meitner, by Fajans, and by Soddy, Cranston, and Fleck. Hahn and Meitner treated *pitchblende* repeatedly with hot nitric acid, and from the insoluble residue, they separated a new radioactive substance, which they called *protoactinium*. The name has since been shortened to *protactinium*. In 1927 Grosse prepared Pa_2O_5, and in 1934 obtained the metal. Protactinium is rarer than radium; it occurs in pitchblende to the extent of about 1 part Pa^{231} to 10 million of ore. Belgian Congo ores have about 3 ppm. The metal has a bright metallic luster which it retains for some time in air. It has twelve known isotopes, the most common of which is Pr^{231} with a half-life of 32,480 years. Some isotopes have a very high neutron cross-section; others have low cross-sections. In 1959 and 1961, it was announced that the Great Britain Atomic Energy Authority extracted by a 12-stage process 125 gms of 99.9% protactinium, the world's only stock of the metal for many years to come. The extraction was made from 60 tons of waste material at a cost of about 500,000 dollars. Protactinium is one of the rarest and most expensive natural-occurring elements. It was reported that this stock was being distributed to laboratories around the world at a cost of about $2800/gm. The element is an alpha emitter (5.0 mev), and is a radiological hazard similar to polonium.

RADIUM (L. *radius*, ray) Ra; at. wt. (226); at. no. 88; m.p. 700°C; b.p. <1737°C; sp. gr. 5?; valence 2. Radium was discovered in 1898 by M. and Mme. Curie in the *pitchblende* or *uraninite* of North Bohemia, in which it occurs. There is about 1 gm. of radium in 7 tons of pitchblende. The element was isolated in 1911 by Mme. Curie and Debierne by the electrolysis of a solution of pure radium chloride, employing a mercury cathode; on distillation in an atmosphere of hydrogen this amalgam yielded the pure metal. Originally, radium was obtained from the rich pitchblende ore found at Joachimsthal, Bohemia. The *carnotite* sands of Colorado furnish some radium, but richer ores are found in the Belgian Congo and in the Great Bear Lake region of Canada. Radium is present in all uranium minerals, and could be extracted, if desired, from the extensive wastes of uranium processing. Large uranium deposits are located in Ontario, New Mexico, Utah, Australia, and elsewhere. Radium is obtained commercially as the bromide or chloride; it is doubtful if any appreciable stock of the isolated element now exists. The pure metal is brilliant white when freshly prepared, but blackens on exposure to air, probably due to formation of the nitride. It exhibits luminescence, as do its salts; it decomposes in water and is somewhat more volatile than barium. It is a member of the alkaline-earth group of metals. Radium imparts a carmine red color to a flame. Radium emits alpha, beta, and gamma rays and when mixed with beryllium produces neutrons. Thirteen isotopes are now known; radium–226, the common isotope, has a half-life of 1620 yrs. One gram of radium produces about 0.0001 milliliter (stp) of emanation, or radon gas, per day. This is pumped from the radium and sealed in minute tubes, which are used in the treatment of cancer and other diseases. One gram of radium yields about 1000 cal. of heat per year. Radium is used in producing self-luminous paints, neutron sources, and in medicine for the treatment of disease. Some of the more recently discovered radioisotopes, such as Co^{60}, are now being used in place of radium. Some of these sources are much more powerful, and others are safer to use. Radium loses about 1% of its activity in 25 yrs., being transformed into elements of lower atomic weight. Lead is a final product of disintegration. The study of radium has greatly altered our ideas of the structure of the atom. Radium is a radiological hazard. (Stored radium should be ventilated to prevent build-up of radon.) Inhalation, injection, or body exposure to radium can cause cancer and other body disorders. The recommended maximum allowable concentration for total body content is 0.1 microgram and exposure to 2 roentgens/mo. Radium in the form of the chloride or bromide is available without A.E.C. permit at a cost of about 25 dollars to 50 dollars/milligram, plus service charges.

RADON (from *radium;* called *niton* at first, L. *nitens*, shining), Rn; at. wt. (~222); at. no. 86; m.p. −71°C; b.p. −61.8°C; density of gas 9.73 gms/l; sp. gr. liquid 4.4 at −62°C, solid 4; valence 0. The element was discovered in 1900 by Dorn, who called it *radium emanation*. In 1908 Ramsay and Gray, who named it *niton*, isolated the element and determined its density, finding it to be the heaviest known gas. It is inert and occupies the last place in the zero group of gases in the Periodic Table. Since 1923, it has been called radon. Eighteen isotopes are known. Radon–222, coming from radium, has a half-life of 3.823 days and is an alpha emitter; radon–220, emanating naturally from thorium and called *thoron*, has a half-life of 54.5 seconds and is also an alpha emitter. Radon–219, emanates from actinium and is called *actinon*. It has a half-life of 3.92 seconds and is both an alpha and gamma emitter. It is estimated that every square mile of soil to a depth of 6 inches contains about 1 gm of radium, which releases radon in tiny amounts to the atmosphere. On the average, one part of radon is present to 1 sextillion parts of air. At ordinary temperatures radon is a colorless gas; when cooled below the freezing point, radon exhibits a brilliant phosphorescence which becomes yellow as the temperature is lowered and orange-red at the temperature of liquid air. It has been reported that fluorine reacts with radon, forming radon fluoride. Radon is still produced for therapeutic use by a

few hospitals by pumping it from a radium source and sealing it in minute tubes, called seeds or needles, for application to patients. This practice is now largely discontinued as hospitals can order the seeds directly from suppliers, who make up the seeds with the desired activity for the day of use. Radon is available at a cost of about 4 dollars/millicurie. Care must be taken in handling radon, as with other radioactive materials. The main hazard is from inhalation of the element and its solid daughters, which are collected on dust in the air. The permissible level in air has been given at 10^{-8} microcuries/milliliter. Good ventilation should be provided where radium, thorium, or actinium is stored to prevent buildup of this element.

RHENIUM (L. *Rhenus*, Rhine), Re; at. wt. 186.2; at. no. 75; m.p. 3180°C; b.p. 5627°C (est.); sp. gr. 21.02 (20°C); valence −1, 2, 3, 4, 5, 6, 7. Discovery of rhenium is generally attributed to Noddack, Tacke, and Berg, who announced in 1925 they had detected the element in platinum ores and *columbite*. They also found the element in *gadolinite* and *molybdenite*. By working up 660 kg. of molybdenite they were able in 1928 to extract 1 gm of rhenium. The price in 1928 was 10,000 dollars/gm. Rhenium does not occur free in nature or as a compound in a distinct mineral species. It is, however, widely spread throughout the earth's crust to the extent of about 0.001 ppm. Commercial rhenium in the U.S. today is obtained from molybdenite roaster-flue dusts obtained from copper-sulfide ores mined in the vicinity of Miami, Arizona, and elsewhere in Arizona and Utah. Some molybdenites contain from 0.002 to 0.2% rhenium. Some 100 lbs. of rhenium are now being produced yearly in powder and fabricated forms by one U.S. company. The total estimated free-world reserve of rhenium metal is 100 tons. Rhenium metal is prepared by reducing ammonium perrhenate with hydrogen at elevated temperatures. The element is silvery white with a metallic luster; its density is exceeded only by that of platinum, iridium, and osmium; and its melting point is exceeded only by that of tungsten and carbon. It has other useful properties. The usual commercial form of the element is as a powder, but it can be consolidated by pressing and resistance-sintering in a vacuum or hydrogen atmosphere. This produces a compact shape in excess of 90% of the density of the metal. Annealed rhenium is very ductile, and can be bent, coiled, or rolled. Rhenium is used as an additive to tungsten and molybdenum-based alloys to impart useful properties. It is widely used for filaments for mass spectrographs and ion gages. Rhenium-molybdenum alloys are superconductive at 10°K. Rhenium is also used as an electrical contact material as it has good wear resistance and withstands arc corrosion. Thermocouples made of Re-W are used for measuring temperatures up to 2200°C, and rhenium wire is used in photoflash lamps for photography. Rhenium powder sells for about 2 dollars/gm or 600 dollars/lb. Fabricated rhenium strip sells for about 800 dollars to 1500 dollars/lb.

RHODIUM (Gr. *rhodon*, rose), Rh; at. wt. 102.905; at. no. 45; m.p. 1966 ± 3°C; b.p. 3727 ± 100°C; sp. gr. 12.41 (20°C); valence 2, 3, 4, or 5. Wollaston discovered rhodium in 1803–4 in crude platinum ore he presumably obtained from South America. Rhodium occurs native with other platinum metals in river sands of the Urals and in North and South America. It is also found with other platinum metals in the copper-nickel sulfide ores of the Sudbury, Ontario, region. Although the quantity occurring here is very small, the large tonnages of nickel processed makes the recovery commercially feasible. The metal is silvery white and at red heat slowly changes in air to the sesquioxide. At higher temperatures it converts back to the element. Rhodium has a higher melting point and lower density than platinum. Its major use is as an alloying agent to platinum. Such alloys are used for furnace windings, thermocouple elements, bushings for glass fiber production, electrodes for aircraft spark plugs, and laboratory crucibles. It is useful as an electrical contact material as it has a low electrical resistance, a low and stable contact resistance, and is highly resistant to corrosion. Plated rhodium, produced by electroplating or

evaporation, is exceptionally hard and is used for optical instruments. It has a high reflectance and is hard and durable. Rhodium is also used for jewelry, for decoration, and as a catalyst. The present cost of rhodium in small quantities is about 7 dollars/gm or 140 dollars/troy ounce.

RUBIDIUM (L. *rubidius*, deepest red), Rb; at. wt. 85.47; at. no. 37; m.p. 38.89°C; b.p. 688°C; sp. gr. (solid) 1.532 (20°C), (liquid) 1.475 (39°C); valence 1, 2, 3, 4. Discovered in 1861 by Bunsen and Kirchoff in the mineral *lepidolite* by use of the spectroscope. The element is much more abundant than was thought several years ago. It is now considered to be the 16th most abundant element in the earth's crust. Rubidium occurs in *pollucite*, *carnallite*, *leucite*, and *zinnwaldite*, which contain traces up to 1%, in the form of the oxide. It is found in lepidolite to the extent of about 1.5%, and is recovered commercially from this source. Potassium minerals, such as those found at Searles Lake, California, and potassium chloride recovered from brines in Michigan also contain the element and are commercial sources. Rubidium can be liquid at room temperature. It is a soft, silvery-white metallic element of the alkali group and is the second most electropositive and alkaline element. It ignites spontaneously in air and reacts violently in water, setting fire to the liberated hydrogen. As with other alkali metals, it forms amalgams with mercury and it alloys with gold, cesium, sodium, and potassium. It colors a flame yellowish violet. It is prepared by electrolysis of the chloride or cyanide, and by other methods. It must be kept under a dry mineral oil or in a vacuum or inert atmosphere. Seventeen isotopes of rubidium are known. Natural-occurring rubidium is made of two isotopes Rb^{85} and Rb^{87}. Rubidium–87 is present to the extent of 27.85% in natural rubidium and is a beta emitter with a half-life of 6×10^{10} yrs. Ordinary rubidium is sufficiently radioactive to expose a photographic film in about 30 to 60 days. Rubidium forms four oxides: Rb_2O, Rb_2O_2, Rb_2O_3, Rb_2O_4. Because rubidium can be easily ionized, it is being considered for use in "ion engines" for space vehicles; however cesium is somewhat more efficient for this purpose. It is also proposed for use as a working fluid for vapor turbines and for use in a thermoelectric generator using the magnetohydrodynamic principle where rubidium ions are formed by heat at high temperature and passed through a magnetic field. These conduct electricity and act like an armature of a generator and cause electricity to be generated. Rubidium is used as a getter in vacuum tubes and as a photocell component. It has been used in making special glasses. The present cost in small quantities is about 7 dollars/gm (99.9%). In large quantities the cost might be less than 100 dollars/lb.

RUTHENIUM (L. *Ruthenia*, Russia), Ru; at. wt. 101.07; at. no. 44; m.p. 2250°C; b.p. 3900°C; sp. gr. 12.41 (20°C); valence 0,1,2,3,4,5,6,7,8. Berzelius and Osann in 1827 examined the residues left after dissolving crude platinum from the Ural Mts. in *aqua regia*. While Berzelius found no unusual metals, Osann thought he found three new metals, one of which he named ruthenium. In 1844 Klaus, generally recognized as the discoverer, showed that Osann's ruthenium oxide was very impure and that it contained a new metal. Klaus obtained 6 gms of ruthenium from the portion of crude platinum that is insoluble in aqua regia. A member of the platinum group, ruthenium occurs native with other members of the group in ores found in the Ural Mts. and in North and South America. It is also found along with other platinum metals in small but commercial quantities in *pentlandite* of the Sudbury, Ontario, nickel-mining region, and in *pyroxinite* deposits of South Africa. The metal is isolated commercially by a complex chemical process, the final stage of which is the hydrogen reduction of ammonium ruthenium chloride, which yields a powder. The powder is consolidated by powder metallurgy techniques or by argon-arc welding. Ruthenium is a hard, white metal and has four crystal modifications. It does not tarnish at room temperatures, but oxidizes in air at about 800°C. The metal is not attacked by hot or cold acids or aqua regia, but when potassium chlorate is added to the solution, it oxidizes explosively. It is attacked by halogens, hydroxides, etc. Ruthenium can be plated

by electrodeposition or by thermal decomposition methods. The metal is one of the most effective hardeners for platinum and palladium, and is alloyed with these metals to make electrical contacts for severe wear resistance. A ruthenium-molybdenum alloy is said to be superconductive at 10.6°K. The corrosion resistance of titanium is improved a hundredfold by addition of 0.1% ruthenium. It is a versatile catalyst. The metal is priced at about 4 dollars/gm or 60 dollars/troy ounce.

SAMARIUM (*Samarskite*, a mineral), Sm; at. wt. 150.35; at. no. 62; m.p. 1072°C; b.p. 1900°C; sp. gr. (α) 7.536, (β) 7.40; valence 2 or 3. Discovered spectroscopically by its sharp absorption lines in 1879 by Lecoq de Boisbaudran in the mineral *samarskite*, named in honor of a Russian mine official, Col. Samarski. Samarium is found along with other members of the rare-earth elements in many minerals, including *monazite* and *bastnaesite*, which are commercial sources. It occurs in monazite to the extent of 2.8%. While *misch metal*, containing about 1% of samarium metal, has long been used, samarium has not been isolated in relatively pure form until recent years. Ion exchange techniques have recently simplified separation of the rare earths from one another; more recently, electrochemical deposition, using an electrolytic solution of lithium citrate and a mercury electrode, is said to be a simple, fast, and highly specific way to separate the rare earths. Samarium metal can be produced by reducing the oxide with barium or lanthanum. Samarium has a bright silver luster and is reasonably stable in air. Two crystal modifications of the metal exist, with a transformation pt. at 917°C. The metal ignites in air at about 150°C. Seventeen isotopes of samarium exist. Samarium, along with other rare earths, is used for carbon-arc lighting for the motion-picture industry. The sulfide has excellent high-temperature stability and good thermoelectric efficiencies up to 1100°C. Samarium is used to dope calcium fluoride crystals for use in optical masers or lasers. Compounds of the metal act as sensitizers for phosphors excited in the infrared; the oxide exhibits catalytic properties in the dehydration and dehydrogenation of ethyl alcohol. It is used in infrared absorbing glass and as a neutron absorber in nuclear reactors. The metal is priced at about 75 cents/gm or 150 dollars/lb.

SCANDIUM (L. *Scandia*, Scandinavia), Sc; at. wt. 44.956; at. no. 21; m.p. 1539°C; b.p. 2727°C; sp. gr. 2.992; valence 3. On the basis of the Periodic System, Mendeleev predicted the existence of *ekaboron*, which would have an atomic weight between 40 of calcium and 48 of titanium. The element was discovered by Nilson in 1879 in the minerals *euxenite* and *gadolinite*, which had not yet been found anywhere except in Scandanavia. By processing 10 kg of euxenite and other residues of rare-earth minerals, Nilson was able to prepare about 2 gms of scandium oxide of high purity. Cleve later pointed out that Nilson's scandium was identical with Mendeleev's ekaboron. Scandium is apparently a much more abundant element in the sun and certain stars than here on earth. It is about the 23rd most abundant element in the sun compared to the 50th most abundant on earth. It is widely distributed on earth, occurring in very minute quantities in over 800 mineral species. The blue color of beryl (aquamarine variety) is said to be due to scandium. It occurs as a principal component in the rare mineral *thortveitite*, found in Scandinavia and Malagazy. It is also found in the residues remaining after the extraction of tungsten from Zinnwald *wolframite*, and in *wiikite* and *bazzite*. Most scandium is presently being recovered as a by-product of the extraction of uranium from *davidite*, which contains about 0.02% Sc_2O_3. Metallic scandium was first prepared in 1938 by Fischer, Brunger, and Grieneisen, who electrolyzed a eutectic melt of potassium, lithium, and scandium chlorides at 700–800°C. Tungsten wire and a pool of molten zinc served as the electrodes in a graphite crucible. Methods of producing the metal are now somewhat more complicated. The production of the first pound of 99% pure scandium metal was announced in 1960 as having been made under a U.S. Air Force contract. Scandium is becoming more readily available and it is reported that many pounds of the metal have now been prepared.

Scandium is a silvery white metal which develops a slightly yellowish or pinkish cast upon exposure to air. It is relatively soft, and is reported to resemble yttrium and the rare-earth metals more than it resembles aluminum or titanium. It is a very light metal and has a higher melting point than aluminum, making it of interest to designers of space missiles. Scandium oxide is now being produced in quantity and is available at a cost of about 3 dollars to 100 dollars/gm, depending on purity, quantity, and supplier. The metal is still relatively expensive, costing about 60 to 150 dollars or more per gram, depending on the purity and supplier.

SELENIUM (Gr. *Selene*, moon), Se; at. wt. 78.96; at. no. 34; m.p. (gray) 217°C; b.p. (gray) 684.9 ± 1.0°C; sp. gr. (gray) 4.79, (vitreous) 4.28; valence 2, 4, or 6. Discovered by Berzelius in 1817, who found it associated with tellurium, named for the earth. Selenium is found in a few rare minerals, such as *crooksite* and *clausthalite*. In years past it has been obtained from flue dusts remaining from processing copper sulfide ores, but the anode muds from electrolytic copper refineries now provide the source of most of the world's selenium. Selenium is recovered by roasting the muds with soda or sulfuric acid, or by smelting them with soda and niter. Selenium exists in several allotropic forms. Three are generally recognized, but as many as six have been claimed. Selenium can be prepared with either an amorphous or crystalline structure. The color of amorphous selenium is either red, in powder form, or black, in vitreous form. Crystalline monoclinic selenium is a deep red; crystalline hexagonal selenium, the most stable variety, is a metallic gray. The element is a member of the sulfur family and resembles sulfur both in its various forms and in its compounds. Selenium exhibits both photovoltaic action, where light is converted directly into electricity, and photo-conductive action, where the electrical resistance decreases with increased illumination. These properties make selenium useful in the production of photocells and exposure meters for photographic use, as well as solar cells. Selenium is also able to convert a.c. electricity to d.c., and is extensively used in rectifiers. Below its melting point selenium is a p-type semiconductor, and is finding many uses in electronic and solid state applications. It is used in Xerography for reproducing and copying documents, letters, etc. It is used by the glass industry to decolorize glass and to make ruby-colored glasses and enamels. It is also used as a photographic toner, and as an additive to stainless steel. Elemental selenium has been said to be practically nontoxic; however, hydrogen selenide and other selenium compounds are extremely toxic, and resemble arsenic in its physiological reactions. Hydrogen selenide in a concentration of 1.5 ppm. is intolerable to man. Selenium occurs in some soils in amounts sufficient to produce serious effects on animals feeding on plants, such as locoweed, grown in such soils. The maximum allowable concentration of selenium compounds in air has been recommended to be 0.1 mg/cu meter. Selenium is priced at about 7 dollars/lb. It is also available in high-purity form at a somewhat higher cost.

SILICON (L. *silex, silicis*, flint), Si; at. wt. 28.086; at. no. 14; m.p. 1410°C; b.p. 2355°C; sp. gr. 2.33 (25°C); valence 4. Davy in 1800 thought silica to be a compound and not an element; later in 1811, Gay Lussac and Thenard probably prepared impure amorphous silicon by heating potassium with silicon tetrafluoride. Berzelius, generally credited with the discovery, in 1824 succeeded in preparing amorphous silicon by the same general method as used earlier, but he purified the product by removing the fluosilicates by repeated washings. Deville in 1854 first prepared crystalline silicon, the second allotropic form of the element. Silicon is present in the sun and stars and is a principal component of a class of meteorites known as *aerolites*. It is also a component of *tektites*, a natural glass of uncertain origin, but believed by many to be meteoritic. Silicon makes up 25.7% of the earth's crust, by weight, and is the second most abundant element, being exceeded only by oxygen. Silicon is not found free in nature, but occurs chiefly as the oxide, and as silicates. *Sand, quartz, rock crystal, amethyst, agate, flint, jasper*, and *opal* are some of the forms in

which the oxide appears. *Granite, hornblende, asbestos, feldspar, clay, mica,* etc. are but a few of the numerous silicate minerals. Silicon is prepared commercially by heating silica and carbon in an electric furnace, using carbon electrodes. Several other methods can be used for preparing the element. Amorphous silicon can be prepared as a brown powder, which can be easily melted or vaporized. Crystalline silicon has a metallic luster and grayish color. Hyper-pure silicon can be prepared by the thermal decomposition of ultra-pure trichlorosilane in a hydrogen atmosphere, and by a vacuum float zone process. This product can be doped with boron, gallium, phosphorus, or arsenic, etc. to produce silicon for use in transistors, solar cells, rectifiers, and other solid-state devices which are used extensively in the electronics and space-age industries. Silicon is a relatively inert element, but it is attacked by halogens and dilute alkali. Most acids, except hydrofluoric, do not affect it. Silicones are important products of silicon. They may be prepared by hydrolyzing a silicon organic chloride, such as dimethyl silicon chloride. Hydrolysis and condensation of various substituted chlorosilanes can be used to produce a very great number of polymeric products, or silicones, ranging from liquids to hard, glass-like solids with many useful properties. Elemental silicon transmits more than 95% of all wavelengths of infrared, from 1.3 to 6.7 microns. Silicon is one of man's most useful elements. In the form of sand and clay it is used to make concrete and brick; it is a useful refractory material for high-temperature work, and in the form of silicates it is used in making enamels, pottery, etc. Silica, as sand, is a principal ingredient of glass, one of the most inexpensive of materials with excellent mechanical, optical, thermal, and electrical properties. Glass can be made in a very great variety of shapes, and is used as containers, window glass, insulators, and thousands of other uses. Silicon is important in plant and animal life. Diatoms in both fresh and salt water extract silica from the water to build up their cell walls. Silica is present in ashes of plants and in the human skeleton. Silicon is an important ingredient in steel; silicon carbide is one of the most important abrasives. Regular grade silicon (97%) costs about 20 cents/lb. Silicon 99.7% pure costs about 7 dollars/lb.; hyper-pure silicon may cost as much as 100 dollars/lb.

SILVER (Anglo-Saxon, *Seolfor, siolfur*), Ag (L. argentum); at. wt. 107.870; at. no. 47; m.p. 960.8°C; b.p. 2212°C; sp. gr. 10.50 (20°C); valence 1, 2. Silver has been known since ancient times. It is mentioned in *Genesis.* Slag dumps in Asia Minor and on islands in the Aegean Sea indicate that man learned to separate silver from lead as early as 3000 B.C. Silver occurs native and in ores, such as *argentite* (Ag_2S) and *horn silver* (AgCl); lead, lead-zinc, copper, gold, and copper-nickel ores are principal sources. Silver is also recovered during electrolytic refining of copper. Commercial fine silver contains at least 99.90% silver. Purities of 99.999+% are available commercially. Pure silver has a brilliant white metallic luster. It is a little harder than gold and is very ductile and malleable, being exceeded only by gold, and perhaps palladium. Pure silver has the highest electrical and thermal conductivity of all metals, and possesses the lowest contact resistance. It is stable in pure air and water, but tarnishes when exposed to ozone, hydrogen sulfide, or air containing sulfur. The alloys of silver are important. Sterling silver is used for jewelry, silverware, etc. where appearance is paramount. This alloy contains 92.5% silver, the remainder being copper or some other metal. Silver is of utmost importance in photography—about 30% of theU.S. industrial consumption going into this application. It is used for dental alloys. Silver is used in making solder and brazing alloys, electrical contacts, and high capacity silver—zinc and silver—cadmium batteries. Silver paints are used for making printed circuits. It is used in mirror production and may be deposited on glass or metals by chemical deposition, electrodeposition, or by evaporation. When freshly deposited, it is the best reflector of visible light known, but it rapidly tarnishes and loses much of its reflectance. It is a poor reflector of ultraviolet. Silver chloride has interesting optical properties as it can be made

transparent; it also is a cement for glass. Silver nitrate, or *lunar caustic*, the most important silver compound, is used in photography and medicine. The price of silver was fixed by the U.S. Treasury at 71 cents/tr. oz. in 1939 and at 90.5 cents in 1946. In November 1961 the U.S. Treasury suspended sales of nonmonetized silver. The return to a free market has caused price fluctuations up to $1.28/tr. oz. The free world consumption of this valuable element in recent years has greatly exceeded the output.

SODIUM (English, *soda;* Medieval Latin, *sodanum*, headache remedy), Na (L. *natrium*); at. wt. 22.9898; at. no. 11; m.p. 97.81 ± 0.03°C; b.p. 892°C; sp. gr. 0.971 (20°C); valence 1. Long recognized in compounds, first isolated by Davy in 1807 by electrolysis of caustic soda. Sodium is present in fair abundance in the sun and stars. The D lines of sodium are among the most prominent in the solar spectrum. Sodium is the sixth most abundant element on earth, comprising about 2.6% of the earth's crust; it is the most abundant of the alkali group of metals of which it is a member. The most common compound is sodium chloride, but it occurs in many other minerals, such as *soda niter, cryolite, amphibole, zeolite, sodalite*, etc. It is a very reactive element and is never found free in nature. It is now obtained commercially by the electrolysis of absolutely dry fused sodium chloride. This method is much cheaper than that of electrolyzing sodium hydroxide, as was used several years ago. Sodium is a soft, bright, silvery metal which floats on water, decomposing it with the evolution of hydrogen and the formation of the hydroxide. It may or may not ignite spontaneously on water, depending on the amount of oxide and metal exposed to the water. It normally does not ignite in air at temperatures below 115°C. Sodium should be handled with respect as it can be dangerous when improperly handled. Metallic sodium is vital in the manufacture of sodamide and sodium cyanide, sodium peroxide, and sodium hydride. It is used in preparing tetraethyl lead, in the reduction of organic esters, and in the preparation of organic compounds. The metal may be used to improve the structure of certain alloys, to descale metal, to purify molten metals, and as a heat transfer agent. An alloy of sodium with potassium, NaK, is also an important heat transfer agent. Sodium compounds are important to the paper, glass, soap, textile, petroleum, chemical and metal industries. Soap is generally a sodium salt of certain fatty acids. Among the many compounds that are of the greatest industrial importance are: common salt (NaCl), soda ash (Na_2CO_3), baking soda ($NaHCO_3$), caustic soda (NaOH), Chile saltpeter ($NaNO_3$), di- and trisodium phosphates, sodium thiosulfate (hypo, $Na_2S_2O_3 \cdot 5H_2O$), and borax ($Na_2B_4O_7 \cdot 10H_2O$). Metallic sodium is priced at about 15 to 20 cents/lb. in quantity. On a per cubic inch basis, it is the cheapest of all metals.

STRONTIUM (*Strontian*, town in Scotland), Sr; at. wt. 87.62; at. no. 38; m.p. 769°C; b.p. 1384°C; sp. gr. 2.54; valence 2. Discovered by Davy by electrolysis in 1808. Strontium is found chiefly as *celestite* ($SrSO_4$) and *strontianite* ($SrCO_3$). The metal can be prepared by electrolysis of the fused chloride mixed with potassium chloride, or is made by reducing strontium oxide with aluminum in a vacuum at a temperature at which strontium distills off. Three allotropic forms of the metal exist, with transition points at 235°C and 540°C. Strontium is softer than calcium and decomposes water more vigorously. It does not absorb nitrogen below 380°C. It should be kept under kerosene to prevent oxidation. Freshly cut strontium has a silvery appearance, but rapidly turns a yellowish color with the formation of the oxide. The finely divided metal ignites spontaneously in air. Volatile strontium salts impart a beautiful crimson color to flames, and these salts are used in pyrotechnics. Strontium has sixteen isotopic forms. Of greatest importance is Sr^{90} with a half-life of 28 yrs. It is a product of nuclear fallout and presents a health problem. This isotope is one of the best long-lived high-energy beta emitters known, and is used in SNAP devices (Systems for Nuclear Auxiliary Power). These devices hold promise for use in space vehicles, remote weather stations, navigational buoys, etc. where a light-weight, long-lived, nuclear-electric power source is needed. Strontium hydroxide, has been used in

sugar refining; however lime is replacing its use as it is cheaper. Strontium titanate is an interesting optical material as it has an extremely high refractive index and an optical dispersion greater than that of diamond. It has been used as a gemstone, but it is very soft. It does not occur naturally. The applications of strontium are similar to those of barium and calcium, but there are few advantages and the cost is much higher. Strontium metal costs about 6 to 8 dollars/lb.

SULFUR (Sanskrit, *sulvere;* L. *sulphurium*), S; at. wt. 32.064; at. no. 16; m.p. (rhombic) 112.8°C, (monoclinic) 119.0°C; b.p. 444.6°C; sp. gr. (rhombic) 2.07, (monoclinic) 1.957 (20°C); valence 2, 4, or 6. Known to the ancients; referred to in Genesis as *brimstone.* Sulfur is found in meteorites. A dark area near the crater Aristarchus on the moon has been studied by R. W. Wood with ultraviolet light. This study suggests strongly that it is a sulfur deposit. Sulfur occurs native in the vicinity of volcanoes and hot springs. It is widely distributed in nature as *iron pyrites, galena, sphalerite, cinnabar, stibnite, gypsum, epsom salts, celestite, barite,* etc. Sulfur is commercially recovered from wells sunk into the salt domes along the Gulf Coast of the U.S. It is obtained from these wells by the Frasch process, which forces heated water into the wells to melt the sulfur, which is then brought to the surface. Sulfur also occurs in natural gas and petroleum crudes and must be removed from these products. Formerly this was done chemically, which wasted the sulfur. New processes now permit recovery, and these sources promise to be very important. Large amounts of sulfur are being recovered from Alberta gas fields. Sulfur is a pale yellow, odorless, brittle solid, which is insoluble in water, but soluble in carbon disulfide. In every state, whether gas, liquid, or solid, elemental sulfur occurs in more than one allotropic form or modification; these present a confusing multitude of forms whose relations are not yet fully understood. Amorphous or "plastic" sulfur is obtained by fast cooling of the crystalline form. Recent x-ray studies indicate that amorphous sulfur may have a helical structure with eight atoms per spiral. Crystalline sulfur seems to be made of rings, each containing eight sulfur atoms, which fit together to give a normal x-ray pattern. Nine isotopic forms of sulfur exist. Four occur in natural sulfur, none of which is radioactive. A finely divided form of sulfur, known as *flowers of sulfur,* is obtained by sublimation. Sulfur readily forms sulfides with many elements. Sulfur is a component of black gunpowder, is used in the vulcanization of natural rubber, and is used as a fungicide. A tremendous tonnage is used to produce sulfuric acid, the most important manufactured chemical. It is used in making sulfite paper and other papers, is used as a fumigant, and in the bleaching of dried fruits. The element is a good electrical insulator. Organic compounds containing sulfur are very important. Sulfur is available in purities of 99.999+ % at about 50 dollars/lb.

TANTALUM (Gr. *Tantalos,* mythological character—father of *Niobe*), Ta; at. wt. 180.948; at. no. 73; m.p. 2996°C; b.p. 5425 ± 100°C; sp. gr. 16.6; valence 2?, 3, 4?, or 5. Discovered in 1802 by Ekeberg, but many chemists thought niobium and tantalum were identical elements until Rose, in 1844, and Marignac, in 1866, indicated and showed that niobic and tantalic acids were two different acids. The early investigators only isolated the impure metal. The first relatively pure ductile tantalum was produced by von Bolton in 1903. Tantalum occurs principally in the mineral *columbite-tantalite* (Fe, Mn) $(Nb, Ta)_2O_6$. Separation of tantalum from niobium requires several complicated steps. Several methods are commercially used to produce the element including: electrolysis of molten potassium fluotantalate, reduction of potassium fluotantalate with sodium, or reacting tantalum carbide with tantalum oxide. Tantalum is a gray, heavy, and very hard metal. When pure, it is ductile and can be drawn into fine wire, which is used as a filament for evaporating metals, such as aluminum. Tantalum is almost completely immune to chemical attack at temperatures below 150°C, and is attacked only by hydrofluoric acid, acidic solutions containing the fluoride ion, and free sulfur trioxide. Alkalis attack it only slowly. At higher temperatures, tantalum becomes much more reactive. The element has a melt-

ing point exceeded only by tungsten and rhenium. Tantalum is used to make a variety of alloys with desirable properties, such as high-melting point, high strength, good ductility, etc. The metal has good "gettering" ability at high temperatures, and tantalum oxide films are stable, and have good rectifying and dielectric properties. Tantalum is used to make electrolytic capacitors, lightning arrestors, and surge suppressors. The metal is widely used to fabricate chemical process equipment, nuclear reactors, aircraft and missile parts, and surgical equipment. Tantalum oxide is used to make special glass with a high index of refraction for camera lenses. The metal has many other uses. The metal in powdered form costs about 35 dollars/lb. Sheet tantalum and fabricated forms are more expensive.

TECHNETIUM (Gr. *technetos*, artificial), Tc; at. wt. (~98); at. no. 43; m.p. 2200 ± 50°C; sp. gr. 11.50 (calc.); valence 3?, 4, 6, or 7. Element 43 was predicted on the basis of the periodic table, and was erroneously reported as having been discovered in 1925, at which time it was named *masurium*. The element was actually discovered by Perrier and Segrè in Italy in 1937. It was found in a sample of molybdenum, bombarded by deuterons in the Berkeley cyclotron, which E. Lawrence sent to these investigators. Technetium was the first element to be produced artificially. Since its discovery, searches for the element in terrestrial materials have been made without success. If it does exist, the concentration must be very small. Surprisingly, it has been found in the spectrum of S, M, and N type stars, and its presence in stellar matter is leading to new theories of the production of heavy elements in the stars. Fourteen isotopes of technetium, with atomic masses ranging from 92 to 105, are known. Tc^{97g} has a half-life of 2.6×10^6 yrs. Tc^{98} has a half-life of 1.5×10^6 yrs. The isotope Tc^{95m}, with a half-life of 60 days, is useful for tracer work, as it produces energetic gamma rays. Technetium has been produced in sufficient quantities to allow isolation of the metal, and production is now said to be in excess of 400 gms./month. The metal was first prepared by passing hydrogen gas at 1100°C over Tc_2S_7. It has since been prepared by heating ammonium pertechnetate and ammonium sulfate in hydrogen gas at 500–600°C. Technetium is a silvery-gray metal that tarnishes slowly in moist air. Until 1960, technetium was available only in small amounts and the price was as high as 2800 dollars per gm. In 1962 it was offered commercially to holders of A.E.C. permits at a price of 90 dollars/gm. Technetium dissolves in nitric acid, aqua regia, and conc. sulfuric acid, but is not soluble in hydrochloric acid of any strength. The element is a remarkable corrosion inhibitor for steel. It is reported that mild carbon steels may be effectively protected by as little as 5 ppm of $KTcO_4$ in aerated distilled water at temperatures up to 250°C. The metal is an excellent superconductor at 11°K and below.

TELLURIUM (L. *tellus*, earth), Te; at. wt. 127.60; at. no. 52; m.p. 449.5 ± 0.3°C; b.p. 989.8 ± 3.8°C; sp. gr. 6.24 (20°C); valence 2, 4, or 6. Discovered by Müller von Reichenstein in 1782; named by Klaproth in 1798. Tellurium is occasionally found native, but is more often found as the telluride of gold and other metals. It is recovered commercially from the anode muds produced during the electrolytic refining of blister copper. Crystalline tellurium has a silvery white appearance, and when pure exhibits a metallic luster. It is brittle and easily pulverized. Amorphous tellurium is formed by precipitating tellurium from a solution of telluric or tellurous acid. Whether this form is truly amorphous, or made of minute crystals, is open to question. Tellurium is a p-type semiconductor, and shows greater conductivity in certain directions, depending on alignment of the atoms. Its conductivity increases slightly with exposure to light. It can be doped with silver, copper, gold, tin, or other elements. In air, tellurium burns with a greenish-blue flame, forming the dioxide. Molten tellurium corrodes iron, copper, and stainless steel. Tellurium and its compounds are probably toxic and should be handled with care. Workmen exposed to as little as 0.01 mg/cu meter of air, or less, develop "tellurium breath," which has a garlic-like odor. Twenty-two isotopes of tellurium are known, with atomic

masses ranging from 114 to 135. Tellurium improves the machinability of stainless steel, and its addition to lead decreases the corrosive action of sulfuric acid to lead and improves its strength and hardness. Tellurium is used in ceramics. Bismuth telluride has been used in thermoelectric devices. One such device, using two Bi-Te semiconductors, is reportedly capable of freezing or boiling water in seconds with the power from two flash-light batteries. The unit is said to be capable of bringing the temperature down to −75°C, using only two amperes of current. Tellurium with a purity of 99.5% costs about 4 dollars/lb. It is also available with purities of 99.999+%.

TERBIUM (*Ytterby*, village in Sweden), Tb; at. wt. 158.924; at. no. 65; m.p. 1356°C; b.p. 2800°C; sp. gr. 8.272; valence 3, 4. Discovered by Mosander in 1843. Terbium is a member of the lanthanide or "rare earth" group of elements. It is found in *cerite*, *gadolinite*, and other minerals along with other rare earths. It is recovered commercially from *monazite* in which it is present to the extent of 0.03% Terbium has been isolated only in recent years with the development of ion-exchange techniques for separating the rare-earth elements. As with other rare earths, it can be produced by reducing the anhydrous chloride or fluoride with calcium metal in a tantalum crucible. Calcium and tantalum impurities can be removed by vacuum remelting. Other methods of isolation are possible. Terbium is reasonably stable in air. It is a silvery gray metal, and is malleable, ductile and soft enough to be cut with a knife. Two crystal modifications exist; eighteen isotopes with atomic masses ranging from 147 to 164 are recognized. The oxide is a chocolate or dark maroon color. Sodium terbium borate is used as a laser material and emits coherent light at 5460Å. Terbium is used to dope calcium fluoride, calcium tungstate, and strontium molybdate, used in solid-state devices. There are few other uses yet found for terbium. The element is priced at about 4 dollars/gm or 750 dollars/lb.

THALLIUM (Gr. *thallos*, a green shoot or twig), Tl; at. wt. 204.37; at. no. 81; m.p. 303.5°C; b.p. 1457 ± 10°C; sp. gr. 11.85 (20°C); valence 1 or 3. Discovered spectroscopically in 1861 by Crookes. The element was named after the beautiful green spectral line, which identified the element. The metal was isolated both by Crookes and Lamy in 1862 about the same time. Thallium occurs in *crooksite*, *lorandite*, and *hutchinsonite*. It is also present in *pyrites* and is recovered from the roasting of this ore in connection with the production of sulfuric acid. It is also obtained from the smelting of lead and zinc ores. Extraction is somewhat complex and depends on the source of the thallium. When freshly exposed to air thallium exhibits a metallic luster, but soon develops a bluish gray tinge, resembling lead in appearance. A heavy oxide builds up on thallium if left in air, and in the presence of water the hydroxide is formed. The metal is very soft and malleable. It can be cut with a knife. Twenty isotopic forms of thallium, with atomic masses ranging from 191 to 210 are recognized. The element and its compounds are toxic and should be carefully handled. Contact of the metal with the skin is dangerous, and when melting the metal, adequate ventilation should be provided. The maximum allowable concentration of soluble thallium compounds in air is 0.1 mg/cu meter. Thallium sulfate is widely employed as a rodenticide and ant killer. It is odorless and tasteless, giving no warning of its presence. The electrical conductivity of thallium sulfide changes with exposure to infrared light and this compound is used in photocells. Thallium bromide-iodide crystals have been used as infrared detectors. Thallium has been used, with sulfur or selenium and arsenic, to produce low melting glasses which become fluid between 125 and 150°C. These glasses have properties at room temperatures similar to ordinary glasses and are said to be durable and insoluble in water. Thallium oxide has been used to produce glasses with a high index of refraction. A mercury–thallium alloy, which forms a eutectic at 8.5% thallium, is reported to freeze at −60°C, some 20°C below the freezing point of mercury. Commercial thallium metal costs about 8 dollars/lb. It is available also in high-purity form.

THORIUM (*Thor*, Scandinavian god of war), Th; at. wt. 232.038; at. no. 90; m.p. ~1700°C; b.p. ~4000°C; sp. gr. ~11.66; valence 4. Discovered by Berzelius in 1828. Thorium occurs in *thorite* ($ThSiO_4$) and in *thorianite* ($ThO_2 + UO_2$). Large deposits of thorium minerals have been reported in New England and elsewhere, but these have not yet been exploited. Thorium is now thought to be about three times as abundant as uranium and about as abundant as lead or molybdenum. The metal is fissionable and is a source of nuclear power. There is probably more energy available for use from thorium in the minerals of the earth's crust than from both uranium and fossil fuels. Thorium is recovered commercially from the mineral *monazite*, which contains from 3 to 9% ThO_2 along with most rare-earth minerals. Several methods are available for producing thorium metal; it can be obtained by reducing thorium oxide with calcium; by electrolysis of anhydrous thorium chloride in a fused mixture of sodium and potassium chlorides; by calcium reduction of thorium tetrachloride mixed with anhydrous zinc chloride; and by reduction of thorium tetrachloride with an alkali metal. When pure, thorium is a silvery-white metal which is air-stable and retains its luster for several months. When contaminated with the oxide, thorium slowly tarnishes in air, becoming gray and finally black. The physical properties of thorium are greatly influenced by the degree of contamination with the oxide. For this reason, values for the melting point and specific gravity are still in question. The purest specimens contain several tenths of a per cent of the oxide. Thorium oxide has a melting point of 3300°C and is the highest of all oxides. Only a few elements, such as tungsten, and a few compounds, such as tantalum carbide, have higher melting points. Thorium is slowly attacked by water, but does not dissolve readily in most common acids, except hydrochloric. Powdered thorium metal is often pyrophoric and should be carefully handled. When heated in air, thorium turnings ignite and burn brilliantly with a white light. The principal use of thorium has been in the preparation of the Welsbach mantle, used for portable gas lights. These mantles, consisting of thorium oxide with about 1% cerium oxide and other ingredients, glow with a dazzling light when heated in a gas flame. Thorium is an important alloying element in magnesium, imparting high strength and creep resistance at elevated temperatures. Because thorium has a low work-function and high electron emission, it is used to coat tungsten wire used in electronic equipment. The oxide is also used to control the grain size of tungsten used for electric lamps; it is also used for high-temperature laboratory crucibles. Thirteen isotopes of thorium are known, all of which are radioactive. Thorium–232 occurs naturally and has a half-life of 1.41×10^{10} yrs. It is an α, β and γ emitter. It is sufficiently radioactive to expose a photographic film in a few hours. Thorium can be used as a nuclear fuel, but has not received the attention of uranium, due to the demand for plutonium. Thorium disintegrates with the production of thoron (radon^{220}), which is an alpha emitter and presents a radiation hazard. Good ventilation of areas where thorium is stored or handled is therefore recommended. Thorium and its compounds are subject to licensing and control by the U.S. Atomic Energy Commission. In small lots, thorium metal costs about 2 dollars/gm.

THULIUM (*Thule*, the earliest name for Scandinavia), Tm; at. wt. 168.934; at. no. 69; m.p. 1545°C; b.p. 1727°C; sp. gr. 9.332; valence 2,3. Discovered in 1879 by Cleve. Thulium occurs in small quantities along with other rare earths in a number of minerals. It is obtained commercially from *monazite*, which contains about 0.007% of the element. Thulium is the least abundant of the rare-earth elements, but with new sources recently discovered, it is now considered to be about as rare as silver, gold, or cadmium. Ion-exchange techniques have recently permitted much easier separation of the rare earths, with much lower costs. Thulium metal, only a few years ago, was not obtainable at any cost; in 1950 the oxide sold for 450 dollars/gm. The oxide is now available, however, for 2 dollars/gm in lb. quantities. Thulium can be isolated by reduction of the oxide with lanthanum metal or by calcium reduction of the anhydrous fluoride. The pure metal has a bright, silvery

luster. It is reasonably stable in air, is soft, malleable and ductile, and can be cut with a knife. Sixteen isotopes are known, with atomic masses ranging from 161 to 176. Because of the relatively high price of the metal, thulium has not yet found many practical applications. Thulium metal costs about 7 dollars/gm or 2000 dollars lb.

TIN (Anglo-Saxon, *tin*), Sn (L. *stannum*); at. wt. 118.69; at. no. 50; m.p. 231.89; b.p. 2270°C; sp. gr. (gray) 5.75, (white) 7.31; valence, 2, 4. Known to the ancients. Tin is found chiefly in *cassiterite* (SnO_2). Most of the world's supply comes from Malaya, Bolivia, Indonesia, the Congo, Thailand, and Nigeria. The U.S. produces almost none, although occurrences have been found in Alaska and California. Tin is obtained by reducing the ore with coal in a reverberatory furnace. Ordinary tin is a silvery white metal, is malleable, somewhat ductile, and has a highly crystalline structure. Due to the breaking of these crystals, a "tin cry" is heard when a bar is bent. The element has two or perhaps three allotropic forms. On warming, gray or α tin, with a cubic structure, changes at 13.2°C into white or β tin, the ordinary form of the metal. White tin has a tetragonal structure. Some authorities believe a γ form exists between 161°C and the melting point; however other authorities discount its existence. When tin is cooled below 13.2°C, it changes slowly from white to gray. This change is affected by impurities, such as aluminum and zinc, and can be prevented by small additions of antimony or bismuth. This change from the α to β form is called "the tin pest." There are few if any uses for gray tin. Tin takes a high polish and is used to coat other metals to prevent corrosion or other chemical action. Such tin plate over steel is used in the so-called tin can for preserving food. Alloys of tin are very important. Soft solder, type metal, fusible metal, pewter, bronze, bell metal, Babbitt metal, White metal, die casting alloy, and phosphor bronze are some of the important alloys using tin. Tin resists distilled, sea, and soft tap water, but is attacked by strong acids, alkalis, and acid salts. Oxygen in solution accelerates the attack. When heated in air, tin forms SnO_2, which is feebly acid, forming stannate salts with basic oxides. The most important salt is the chloride ($SnCl_2.H_2O$), which is used as a reducing agent and as a mordant in calico printing. Tin salts sprayed onto glass are used to produce electrically conductive coatings on the glass. These have been used for panel lighting and for frost-free windshields. Of recent interest is a crystalline tin-niobium alloy that is superconductive at very low temperatures. This promises to be important in the construction of superconductive magnets that generate enormous field strengths, but use practically no power. Such magnets, made of tin-niobium wire, weigh but a few pounds and will produce magnetic fields, when started with a small battery, that are comparable to that of a 100-ton electromagnet operated continuously with a large power supply.

TITANIUM (L. *Titans*, the first sons of the Earth, myth.), Ti; at. wt. 47.90; at. no. 22; m.p. 1675°C; b.p. 3260°C; sp. gr. 4.54; valence 2, 3, or 4. Discovered by Gregor in 1791; named by Klaproth in 1795. Impure titanium was prepared by Nilson and Pettersson in 1887; however the pure metal (99.9%) was not made until 1910 by Hunter by heating $TiCl_4$ with sodium in a steel bomb. Titanium is present in meteorites and in the sun. Titanium oxide bands are prominent in the spectra of M Type stars. The element is the ninth most abundant in the crust of the earth. Titanium is almost always present in igneous rocks and in the sediments derived from them. It occurs in the minerals *rutile*, *ilmenite*, and *sphene*, and is present in titanates and in many iron ores. Titanium is present in the ash of coal, in plants, and in the human body. The metal was a laboratory curiosity until Kroll, in 1946, showed that titanium could be produced commercially by reducing titanium tetrachloride with magnesium. This method is largely used for producing the metal today. The metal can be purified by decomposing the iodide. Titanium, when pure, is a lustrous, white metal. It has a low density, good strength, is easily fabricated, and has excellent corrosion resistance. It is ductile only when it is free of oxygen. The metal

burns in air and is the only element that burns in nitrogen. Titanium is resistant to dilute sulfuric and hydrochloric acid, most organic acids, moist chlorine gas, and chloride solutions. The metal is dimorphic. The hexagonal α form changes to the cubic β form very slowly at about 880°C. The metal combines with oxygen at red heat, and with chlorine at 500°C. Titanium is important as an alloying agent with aluminum, molybdenum, manganese, iron, and other metals. Alloys of titanium are principally used for aircraft and missiles where light-weight, strength, and ability to withstand extremes of temperature are important. The metal has excellent resistance to sea water and is used for propeller shafts, rigging, and other parts of ships exposed to salt water. A titanium anode, coated with platinum has been used to provide cathodic protection from corrosion by salt water. Titanium metal is considered to be physiologically inert. When pure, titanium dioxide is relatively clear and has an extremely high index of refraction with an optical dispersion higher than diamond. It is produced artificially for use as a gemstone, but it is relatively soft. Star sapphires and rubies exhibit their asterism as a result of the presence of TiO_2. Titanium dioxide is extensively used for both house paint and artist's paint, as it is permanent and has good covering power. The price of commercial titanium metal is about 6 to 7 dollars/lb.

TUNGSTEN (Swedish, *tung sten*, heavy stone); also known as WOLFRAM (from *wolframite*, said to be named from *wolf rahm* or *spumi lupi*, because the ore interfered with the smelting of tin and was supposed to devour the tin), W; at. wt. 183.85; at. no. 74; m.p. 3410 ± 20°C; b.p. 5927°C; sp. gr. 19.3 (20°C); valence 2, 3, 4, 5, or 6. In 1779 Peter Woulfe examined the mineral now known as *wolframite* and concluded it must contain a new substance. Scheele, in 1781, found that a new acid could be made from *tung sten* (a name first applied about 1758 to a mineral now known as *scheelite*). Scheele and Bergman suggested the possibility of obtaining a new metal by reducing this acid. The de Elhuyar brothers found an acid in *wolframite* in 1783 that was identical to the acid of *tung sten* (tungstic acid) of Scheele, and in that year they succeeded in obtaining the element by reduction of this acid with charcoal. Tungsten occurs in *wolframite*, (Fe, Mn)WO_4; *scheelite*, $CaWO_4$; *huebnerite*, $MnWO_4$; and *ferberite*, $FeWO_4$. Important deposits of tungsten occur in Nevada, California, North Carolina, China, Korea, Bolivia, U.S.S.R., and Portugal. The metal is obtained by reducing tungstic oxide with hydrogen, carbon, carbonaceous gases, or calcium. Pure tungsten is a steel gray to tin-white metal. Very pure tungsten can be cut with a hacksaw, and can be forged, spun, drawn, and extruded. The impure metal is brittle and can be worked only with difficulty. Tungsten has the highest melting point and lowest vapor pressure of all metals, and at temperatures over 1650°C has the highest tensile strength. The metal oxidizes in air and must be protected at elevated temperatures. It has excellent corrosion resistance and is attacked only slightly by most mineral acids. The thermal expansion is about the same as boro-silicate glass, which makes the metal useful for glass-to-metal seals. Tungsten and its alloys are used extensively for filaments for electric lamps, electron and television tubes, and for metal evaporation work; for electrical contact points for automobile distributors; x-ray targets; windings and heating elements for electrical furnaces; and for numerous space missile and high-temperature applications. High-speed tool steels, Hastelloys, Stellite, and many other alloys contain tungsten. Tungsten carbide is of great importance to the metalworking, mining, and petroleum industries. Calcium and magnesium tungstates are widely used in fluorescent lighting; other salts of tungsten are used in the chemical, pigment, and tanning industries. Tungsten disulfide is a dry, high-temperature lubricant, stable to 500°C.

URANIUM (Planet *Uranus*), U; at. wt. 238.03; at. no. 92; m.p. 1132.3 ± 0.8°C; b.p. 3818°C; sp. gr. ~18.95; valence 3, 4, 5, or 6. Yellow-colored glass, containing more than 1% uranium oxide and dating back to 79 A.D., has been found near Naples, Italy. Klaproth recognized an unknown element in *pitchblende* and attempted to isolate the metal

in 1789. The metal apparently was first isolated in 1841 by Peligot, who reduced the anhydrous chloride with potassium. Uranium is not as rare as it was once thought. It is now considered to be more plentiful than mercury, antimony, silver, or cadmium, and is about as abundant as molybdenum or arsenic. It occurs in numerous minerals, such as *pitchblende, uraninite, carnotite, autunite, uranophane, davidite,* and *tobernite.* It is also found in *phosphate rock, lignite, monazite sands,* and can be recovered commercially from these sources. The A.E.C purchases uranium in the form of acceptable concentrates at an established price of $8/lb. of U_3O_8. This incentive program has greatly increased the known uranium reserves. Uranium can be prepared by reducing a uranium halide, such as UF_4 with magnesium or calcium. The metal can also be produced by electrolysis of KUF_5 or UF_4, dissolved in a molten mixture of $CaCl_2$–NaCl. High-purity uranium can be prepared by the thermal decomposition of uranium halides on a hot filament. Uranium exhibits three crystallographic modifications as follows:

$$\alpha \xrightarrow{667^\circ C} \beta \xrightarrow{775^\circ C} \gamma$$

Uranium is a heavy, silvery white metal, which is pyrophoric when finely divided. It is a little softer than steel, and is attacked by cold water in a finely divided state. In air, the metal becomes coated with a layer of oxide. Acids dissolve the metal, but it is unaffected by alkalis. Uranium has fourteen isotopes, all of which are radioactive. Natural-occurring uranium contains 99.28% U^{238}, 0.71% U^{235}, and 0.0058% U^{234}. It is sufficiently radioactive to expose a photographic plate in an hour or so. U^{238}, with a half-life of 4.5×10^9 years, has been used to estimate the age of igneous rocks. The origin of uranium, the highest member of the natural-occurring elements is not clearly understood, although it may be presumed to be a decay product of elements of higher atomic weight, which are produced only by artificial means on earth. Uranium is of great importance as a basic nuclear fuel. U^{235}, the only natural-occurring fissionable material, can be separated from U^{238} by gaseous diffusion processes and by other methods. U^{238} can be converted to fissionable plutonium by the following reactions:

$$_{92}U^{238} + \text{neutron} \rightarrow {}_{92}U^{239} + \gamma$$
$$_{92}U^{239} \rightarrow {}_{93}Np^{239} + \text{electron}$$
$$_{93}Np^{239} \rightarrow {}_{94}Pu^{239} + \text{electron}.$$

One pound of completely fissioned uranium has the fuel value of over 1500 tons of coal. Uranium, to be used as a nuclear fuel, must be "enriched" by increasing the percentage of U^{235} present in a given sample. It is supplied for this purpose in the form of the unalloyed or alloyed metal, or it may be furnished as the oxide, as a compound dissolved in water or a fused salt, or as a liquid-metal solution. Uranium in the U.S.A. is under control of the Atomic Energy Commission. New uses are being explored for "depleted" uranium (i.e. uranium with the percentage of U^{235} lowered or removed); however, it has found relatively few applications. Uranium metal is used for x-ray targets for production of high-energy x-rays; the nitrate has been used as photographic toner; and the acetate is used in analytical chemistry. Uranium salts have also been used for producing yellow "vaseline" glass and glazes. Uranium and its compounds are highly toxic, both from a chemical and radiological standpoint. Finely divided uranium metal, being pyrophoric, presents a fire hazard. The maximum recommended allowable concentration of soluble uranium compounds in air (based on chemical toxicity) is 0.05 mg/cu meter; for insoluble compounds the concentration is set at 0.25 mg/cu meter of air. The permissible body level of natural uranium (based on radiotoxicity) is 0.2 microcurie for soluble compounds; for insoluble compounds the level is 0.009 microcurie, or in air 1.7×10^{-11} microcurie per milliliter.

VANADIUM (Scandinavian goddess, *Vanadis*), V; at. wt. 50.942; at. no. 23; m.p. 1890° ± 10°C; b.p. ~3000°C; sp. gr. 6.11 (18.7°C); valence 2, 3, 4, or 5. Vanadium was

first discovered by del Rio in 1801. Unfortunately a French chemist incorrectly declared del Rio's new element was only impure chromium; del Rio thought himself to be mistaken and accepted the French chemist's statement. The element was rediscovered by Sefström in 1830, and isolated in nearly pure form by Roscoe, in 1867, who reduced the chloride with hydrogen. Vanadium of 99.3 to 99.8% purity was not produced until 1927. Vanadium is found in about 50 different minerals among which are *carnotite, roscoelite, vanadinite,* and *patronite*—important sources of the metal. Vanadium is also found in phosphate rock, certain iron ores, and is present in some crude oils in the form of organic complexes. Commercial production from petroleum ash holds promise as an important source of the element. High-purity vanadium can be obtained by reduction of the oxide with calcium or the trichloride with magnesium. It can also be produced by thermal decomposition methods. Pure vanadium is a bright white metal, and is soft and ductile. It has good corrosion resistance to alkalis, sulfuric and hydrochloric acid, and salt waters, but the metal oxidizes readily above 660°C. The metal has good structural strength and a low-fission neutron cross section, making it useful in nuclear applications. Vanadium is used in producing rust-resistant, spring, and high-speed tool steels. It is an important carbide stabilizer in making steels. Vanadium foil is used as a bonding agent in cladding titanium to steel. Vanadium pentoxide is used in ceramics and as a catalyst. It is also used as a mordant in dyeing and printing fabrics and in the manufacture of aniline black. Vanadium and its compounds should be handled with care. The maximum allowable concentration of V_2O_5 dust in air is about 0.5 mg/cu meter; V_2O_5 fumes should not exceed about 0.1 mg/cu meter of air. Ductile vanadium has recently become commercially available at a cost of about $40/lb. Commercial vanadium metal, of about 95% purity, costs about $5/lb.

WOLFRAM (see Tungsten)

XENON (Gr. *xenon,* stranger); Xe; at. wt. 131.30; at. no. 54; m.p. −111.9°C; b.p. −107.1 ± 3°C; density 5.887 ± 0.009 g/l, sp. gr. (liquid) 3.52 (−109°C); valence 0?. Discovered by Ramsay and Travers in 1898 in the residue left after evaporating liquid air components. Xenon is a member of the so-called rare or "inert" gases. It is present in the atmosphere to the extent of about one part in twenty million. The element is found in the gases evolved from certain mineral springs, and is commercially obtained by extraction from liquid air. Until recently, xenon has been considered inert and unable to form compounds with other elements. Those compounds that were occasionally reported in the literature were considered not to be true compounds. Evidence has been mounting in the past few years that xenon, as well as other members of the zero valence elements, do form compounds. Among the "compounds" of xenon now reported are xenon hydrate, deuterate, difluoride, tetrafluoride, hexafluoride, and $XePtF_6$ and $XeRhF_6$. More recently, xenon trioxide, which is highly explosive, has been prepared. The structure of these substances is still open to question. Xenon in a vacuum tube produces a beautiful blue glow when excited by an electrical discharge. The gas is used in making stroboscopic lamps, bactericidal lamps, and lamps used to excite ruby lasers for generating coherent light. Xenon is used in the atomic energy field in bubble chambers, probes, and other applications where its high molecular weight is of value. It is also potentially useful as a gas for ion engines. Twenty-four isotopes of xenon are recognized. Xe^{133} and Xe^{135} are produced by neutron irradiation in air-cooled nuclear reactors. Xe^{133} has useful applications as a radioisotope. Xenon gas has been used as an experimental surgical anesthetic on human beings. The element is available in sealed glass containers for about $6/100 cc. of gas at standard pressure.

YTTERBIUM (*Ytterby,* village in Sweden), Yb; at. wt. 173.04; at. no. 70; m.p. 824 ± 5°C; b.p. 1427°C; sp. gr. (α) 6.977, (β) 6.54; valence 2, 3. Marignac in 1878 discovered a new component, which he called *ytterbia,* in the earth then known as *erbia.* In 1907, Urbain separated ytterbia into two components, which he called *neoytterbia* and *lutecia.*

The elements in these earths are now known as *ytterbium* and *lutetium*, respectively. These elements are identical with *aldebaranium and cassiopeium* discovered independently and at about the same time by von Welsbach. Ytterbium occurs along with other rare earths in a number of rare minerals. It is commercially recovered principally from *monazite sand*, which contains about 0.03%. Ion-exchange techniques developed in recent years have greatly simplified the separation of the rare earths from one another. It is only in recent years that ytterbium has been isolated in relatively pure form. The element can be prepared by reducing the oxide with lanthanum or misch metal by special techniques. Ytterbium has a bright silvery luster, is soft, malleable, and quite ductile. It is stable in air and reacts only slowly with water. Ytterbium has two allotropic forms with a transformation point at 798°C. Fourteen isotopes are recognized. As yet, because of its relatively high price, very few uses have been found for the metal or its compounds. One isotope is reported to have been used as a radiation source as a substitute for a portable x-ray machine where electricity is unavailable. Ytterbium metal is commercially available with a purity of about 99+% for about $1.50/gm, or $200/lb.

YTTRIUM (*Ytterby*, village in Sweden), Y; at. wt. 88.905; at. no. 39; m.p. 1495° ± 5°C; b.p. 2927°C; sp. gr. 4.45; valence 3. *Yttria*, which is an earth containing yttrium, was discovered by Gadolin in 1794; in 1843 Mosander showed that yttria could be resolved into the earths of three elements. The name yttria was reserved for the most basic one; the others were named *erbia* and *terbia*. Yttrium occurs in nearly all of the rare-earth minerals. It is recovered commercially from *monazite sand*, which contains about 3%, and from *bastnaesite*, which contains about 0.2%. Wöhler obtained the impure element in 1828 by reduction of the anhydrous chloride with potassium. The metal is now produced commercially by reduction of the fluoride with calcium metal in a calcium fluoride-lined bomb, using zinc fluoride as an additive. The metal is produced as a Y-Zn alloy. The zinc is removed by vacuum distillation; the yttrium metal is arc-melted in helium. It can also be prepared by other techniques. Yttrium has a silvery metallic luster and is relatively stable in air. Turnings of the metal, however, ignite readily in air, and finely divided yttrium is very unstable in air. Small amounts of yttrium (0.1 to 0.2%) can be used to reduce the grain size in chromium, molybdenum, zirconium, and titanium, and to increase strength of aluminum and magnesium alloys. Alloys with other useful properties can be obtained by using yttrium as an additive. The metal can be used as a deoxidizer for vanadium and other nonferrous metals. The metal has a low cross section for nuclear capture. Y^{90}, one of the fifteen recognized isotopes of yttrium, exists in equilibrium with its parent Sr^{90}, a product of atomic explosions. Yttrium has been considered for use as a nodulizer for producing nodular cast iron, in which the graphite forms compact nodules instead of the usual flakes. Such iron has increased ductility. Yttrium iron, aluminum, and gadolinium garnets, with formulas such as $Y_3Fe_5O_{12}$ and $Y_3Al_5O_{12}$, have interesting magnetic properties. Such garnets are used in microwave and other electronic applications. Yttrium iron garnet is also exceptionally efficient as both a transmitter and transducer of acoustic energy. Yttrium metal of 99+% purity is commercially available at a cost of about $1/gm or $200/lb.

ZINC (Ger. *Zink*, of obscure origin), Zn; at. wt. 65.37; at. no. 30; m.p. 419.4°C; b.p, 907°C; sp. gr. 7.133 (25°C); valence 2. Zinc ores were used for making brass centuries before zinc was recognized as a distinct element. Tubal-Cain, seven generations from Adam, is mentioned as being an "instructor of every artificer in brass and iron." An alloy containing 87% zinc has been found in prehistoric ruins in Transylvania. Metallic zinc was produced in the 13th Century A.D. in India by reducing calamine with organic substances, such as wool. The metal was rediscovered in Europe by Marggraf in 1746, who showed that the metal could be obtained by reducing *calamine* with charcoal. The principal ores of zinc are *sphalerite* or *blende* (sulfide), *smithsonite* (carbonate), *calamine* (silicate), and *franklinite* (zinc, manganese, iron oxide). Zinc can be obtained by roasting its ores to form the

oxide and by reduction of the oxide with coal or carbon, with subsequent distillation of the metal. Other methods of extraction are possible. Zinc is a bluish-white lustrous metal. It is brittle at ordinary temperatures but malleable at 100° to 150°C. It is a fair conductor of electricity, and burns in air at high red heat with evolution of white clouds of the oxide. The metal is employed to form numerous alloys with other metals. Brass, nickel silver, typewriter metal, commercial bronze, spring brass, German silver, soft solder and aluminum solder are some of the more important alloys. Large quantities of zinc are used to produce die castings, used extensively by the automotive, electrical, and hardware industries. Zinc is also extensively used to galvanize other metals, such as iron, to prevent corrosion. Neither zinc nor zirconium is ferromagnetic, but $ZrZn_2$ exhibits ferromagnetism at temperatures below 35°K. Zinc oxide is a unique and very useful material to modern civilization. It is widely used in the manufacture of paints, rubber products, cosmetics, pharmaceuticals, floor coverings, plastics, printing inks, soap, storage batteries, textiles, electrical equipment, and other products. It has unusual electrical, thermal, optical, and solid-state properties that have not yet been fully investigated. Lithopone, a mixture of zinc sulfide and barium sulfate, is an important pigment. Zinc sulfide is used in making luminous dials, X-ray and TV screens, and fluorescent lights. The chloride and chromate are also important compounds.

ZIRCONIUM (Arabic *zargun*, gold color), Zr; at. wt. 91.22; at. no. 40; m.p. 1852 ± 2°C; b.p. 3578°C; sp. gr. 6.53 ± 0.01 (calc.). The name *zircon* probably originated from the arabic word *zargun*, which describes the color of the gemstone now known as *zircon*, *jargon*, *hyacinth*, *jacinth*, or *ligure*. This mineral, or its variations, is mentioned in biblical writings. The mineral was not known to contain a new element until Klaproth, in 1789, analyzed a jargon from Ceylon and found a new earth, which Werner named zircon (*silex circonius*), and Klaproth called *Zirkonerde* (*zirconia*). The impure metal was first isolated by Berzelius in 1824 by heating a mixture of potassium and potassium zirconium fluoride in a small iron tube. Pure zirconium was first prepared in 1914. Zirconium is found in abundance in S-type stars, and has been identified in the sun and meteorites. Zircon, $ZrSiO_4$, the principal ore, is found in deposits in Florida, South Carolina, Australia, and Brazil. Zirconium also occurs in some 30 other recognized mineral species. Zirconium is produced commercially by reduction of the chloride with magnesium (the Kroll Process), and by other methods. It is a grayish-white lustrous metal. When finely divided, the metal will ignite spontaneously in air. The solid metal is much more difficult to ignite. The inherent toxicity of zirconium compounds is low. Hafnium is invariably found in zirconium ores, and the separation is difficult. Commercial-grade zirconium contains from 1 to 3% hafnium. Zirconium has a low absorption cross section for neutrons, and is therefore used for nuclear energy applications, such as for cladding fuel elements. Reactor-grade zirconium is essentially free of hafnium. Zircaloy is an important alloy developed specifically for nuclear applications. Zirconium is exceptionally resistant to corrosion by common acids and alkalis, by sea water, and by other agents. It is used extensively by the chemical industry where corrosive agents are employed. Zirconium is used as a getter in vacuum tubes, as an alloying agent in steel, in making surgical appliances, photoflash bulbs, explosive primers, rayon spinnerets, lamp filaments etc. It is used in poison ivy lotions as the carbonate as it combines with urushiol. With columbium, zirconium is superconductive at low temperatures and is used to make superconductive magnets, which offer hope of direct large-scale generation of electric power. Alloyed with zinc, zirconium becomes magnetic at temperatures below 35°K. Zirconium oxide (zircon) has a high index of refraction and is used as a gem material. The impure oxide, zirconia, is used for laboratory crucibles that will withstand heat shock, for linings of metallurgical furnaces, and by the glass and ceramic industries as a refractory material. Commercial zirconium metal sponge is priced at about $5/lb; reactor grade sponge at about $7/lb. Fabricated zirconium parts may be much higher in cost.

1. ELEMENTS

1.1. Names and Symbols of the Elements

1.11.—The elements should have the symbols given in the following table (Table I). It is desirable that the names should differ as little as possible among the different languages, but as complete uniformity is hard to achieve, separate lists have been drawn up in English and in French. The English list only is reproduced here.

TABLE I

ELEMENTS

Name	Symbol	Atomic number	Name	Symbol	Atomic number	Name	Symbol	Atomic number
Actinium	Ac	89	Gold (Aurum)	Au	79	Praseodymium	Pr	59
Aluminum	Al	13	Hafnium	Hf	72	Promethium	Pm	61
Americium	Am	95	Helium	He	2	Protactinium	Pa	91
Antimony	Sb	51	Holmium	Ho	67	Radium	Ra	88
Argon	Ar	18	Hydrogen	H	1	Radon	Rn	86
Arsenic	As	33	Indium	In	49	Rhenium	Re	75
Astatine	At	85	Iodine	I	53	Rhodium	Rh	45
Barium	Ba	56	Iridium	Ir	77	Rubidium	Rb	37
Berkelium	Bk	97	Iron (Ferrum)	Fe	26	Ruthenium	Ru	44
Beryllium	Be	4	Krypton	Kr	36	Samarium	Sm	62
Bismuth	Bi	83	Lanthanum	La	57	Scandium	Sc	21
Boron	B	5	Lead (Plumbum)	Pb	82	Selenium	Se	34
Bromine	Br	35	Lithium	Li	3	Silicon	Si	14
Cadmium	Cd	48	Lutetium	Lu	71	Silver (Argentum)	Ag	47
Calcium	Ca	20	Magnesium	Mg	12	Sodium	Na	11
Californium	Cf	98	Manganese	Mn	25	Strontium	Sr	38
Carbon	C	6	Mendelevium	Md	101	Sulfur	S	16
Cerium	Ce	58	Mercury	Hg	80	Tantalum	Ta	73
Cesium	Cs	55	Molybdenum	Mo	42	Technetium	Tc	43
Chlorine	Cl	17	Neodymium	Nd	60	Tellurium	Te	52
Chromium	Cr	24	Neon	Ne	10	Terbium	Tb	65
Cobalt	Co	27	Neptunium	Np	93	Thallium	Tl	81
Copper (Cuprum)	Cu	29	Nickel	Ni	28	Thorium	Th	90
Curium	Cm	96	Niobium	Nb	41	Thulium	Tm	69
Dysprosium	Dy	66	Nitrogen	N	7	Tin (Stannum)	Sn	50
Einsteinium	Es	99	Nobelium	No	102	Titanium	Ti	22
Erbium	Er	68	Osmium	Os	76	Tungsten (Wolfram)	W	74
Europium	Eu	63	Oxygen	O	8	Uranium	U	92
Fermium	Fm	100	Palladium	Pd	46	Vanadium	V	23
Fluorine	F	9	Phosphorus	P	15	Xenon	Xe	54
Francium	Fr	87	Platinum	Pt	78	Ytterbium	Yb	70
Gadolinium	Gd	64	Plutonium	Pu	94	Yttrium	Y	39
Gallium	Ga	31	Polonium	Po	84	Zinc	Zn	30
Germanium	Ge	32	Potassium	K	19	Zirconium	Zr	40

◆The committees reaffirm the name niobium for element 41 in spite of the fact that many in the United States, particularly outside of chemical circles, still retain the name columbium.

1.12.—The names placed in parentheses (after the trivial names) in the list in Table I shall always be used when forming names derived from those of the elements, *e.g.*, aurate, ferrate, wolframate and not goldate, ironate, tungstate.

For some compounds of sulfur, nitrogen, and antimony, derivatives of the Greek name *θεῖον*, the French name *azote*, and the Latin name *stibium*, respectively, are used.

Although the name nickel agrees with the chemical symbol, it is essentially a trivial name and is spelled so differently in various languages (niquel, nikkel, *etc.*) that it is recommended that names of derivatives be formed from the Latin name *niccolum*, *e.g.*, niccolate instead of nickelate. The name mercury should be used as the root name also in languages where the element has another name (mercurate, *not* hydrargyrate).

In the cases in which different names have been used, the Commission has selected one based upon considerations of prevailing usage and practicability. It should be emphasized that their selection carries no implication regarding priority of discovery.

◆Tungstate and nickelate are both so well established in American practice that the committees object to changing them to wolframate and niccolate.

1.13.—Any new metallic elements should be given names ending in -ium. Molybdenum and a few other elements have long been spelled without an "i" in most languages, and the Commission hesitates to insert it.

1.14.—All new elements shall have two-letter symbols.

1.15.—All isotopes of an element should have the same name. For hydrogen the isotope names protium, deuterium, and tritium may be retained, but it is undesirable to assign isotopic names instead of numbers to other elements. They should be designated by mass numbers as, for example, "oxygen-18."

◆The list in 3.21 implies that D is an acceptable symbol for deuterium, whereas ^2H is used in 1.32. It is recommended that D and T be allowed for deuterium and tritium, respectively. *Cf.* comments made at 1.31, 1.32.

1.2. Names for Groups of Elements and their Subdivisions

1.21.—The use of the collective names: halogens (F, Cl, Br, I, and At), chalcogens (O, S, Se, Te, and Po), and halides and chalcogenides for their compounds, alkali metals (Li to Fr), alkaline earth metals (Ca to Ra), and inert gases may be continued. The name rare earth metals may be used for the elements Sc, Y, and La to Lu inclusive; the name lanthanum series for the elements no. 57–71 (La to Lu inclusive), and the name lanthanides for the elements 58–71 (Ce to Lu inclusive) are recommended. Elements no. 89 (Ac) to 103 form the actinium series, and the name actinides is reserved for the elements in which the 5*f* shell is being filled. The name transuranium elements is also approved for the elements following uranium.

◆The collective term halogenides used in the Rules has been replaced in this version by halides, which is almost universally used in English and is unambiguous.

The inclusion of Sc with the rare earths is questioned by some. No need is seen for the terms lanthanum series and actinium series, particularly since the latter term is used for a radioactive series. The use of a collective term for elements 58–71 is approved, although it is suggested that lanthan*oid* is preferable to lanthan*ide* because of the use of -ide for binary compounds; similarly, actin*oid* is preferable to actin*ide*. Definition by means of atomic numbers is recommended in both cases rather than on the basis of interpretation (*e.g.*, filling of 5*f* shells).

1.22.—The word metalloid should not be used to denote nonmetals.

1.3. Indication of Mass, Charge, etc., on Atomic Symbols

1.31.—The mass number, atomic number, number of atoms, and ionic charge of an element may be indicated by means of four indices placed around the symbol. The positions are to be occupied thus

left upper index	right lower index	mass number	number of atoms
left lower index	right upper index	atomic number	ionic charge

Ionic charge should be indicated by A^{n+} rather than by A^{+n}.

Example: ${}^{32}_{16}S^{2+}_{2}$ represents a doubly ionized molecule containing two atoms of sulfur, each of which has the atomic number 16 and mass number 32.

The following is an example of an equation for a nuclear reaction

$$ {}^{26}_{12}Mg + {}^{4}_{2}He = {}^{29}_{13}Al + {}^{1}_{1}H $$

◆Although the practice of American chemists and physicists in general has been to put the mass number at the upper right of the symbol, the committees recognize the advantage of putting it at the upper left so that the upper right is available for the ionic charge as needed.

1.32.—Isotopically labeled compounds may be described by adding to the name of the compounds the symbol of the isotope in parentheses.

Examples:

$^{32}PCl_3$ phosphorus(^{32}P) trichloride (spoken: phosphorus-32 trichloride)

$H^{36}Cl$ hydrogen chloride^{36}(Cl) (spoken: hydrogen chloride-36)

$^{15}NH_3$ ammonia(^{15}N) (spoken: ammonia nitrogen-15)

The position of the labeled atom may be indicated by placing the isotope symbol immediately after the locant (name of the group concerned).

Example: $^{2}H_2{}^{35}SO_4$ sulfuric(^{35}S) acid(^{2}H)

If this method gives names which are ambiguous or difficult to pronounce, the whole group containing the labeled atom may be indicated.

Examples:

$HOSO_2{}^{35}SH$	thiosulfuric(^{35}SH) acid
$^{15}NO_2NH_2$	nitramide($^{15}NO_2$), not nitr(^{15}N)amide
$NO_2{}^{15}NH_2$	nitramide($^{15}NH_2$)
$HO_3S^{18}O{-}^{18}OSO_3H$	peroxo($^{18}O_2$)disulfuric acid

1.4. Allotropes

If systematic names for gaseous and liquid modifications are required, they should be based on the size of the molecule, which can be indicated by Greek numerical prefixes (listed in 2.251). If the number of atoms is large and unknown, the prefix poly may be used. To indicate ring and chain structures the prefixes cyclo and catena may be used.

Examples:

Symbol	Trivial Name	Systematic Name
H	atomic hydrogen	monohydrogen
O_2	(common) oxygen	dioxygen
O_3	ozone	trioxygen
P_4	white phosphorus (yellow phosphorus)	tetraphosphorus
S_8	λ-sulfur	cycloöctasulfur or octasulfur
S_n	μ-sulfur	catenapolysulfur or polysulfur

For the nomenclature of solid allotropic forms the rules in Section 8 may be applied.

◆The use of prefixes to indicate ring and chain structures is favored by the committees, but it should be pointed out that ino (not catena) has been used by mineralogists for indicating chain structures in silicates, along with cyclo and other prefixes (neso, phyllo, tecto, soro) denoting structure, all used without italics or hyphens (*e.g.*, inosilicates). *Cf.* use of catena in 7.42 for chains of alternating, not self-linking, atoms.

2. FORMULAS AND NAMES OF COMPOUNDS IN GENERAL

Many chemical compounds are essentially binary in nature and can be regarded as combinations of ions or radicals; others may be treated as such for the purpose of nomenclature.

Some chemists have expressed the opinion that the name of a compound should indicate whether it is ionic or covalent. Such a distinction is made in some languages (*e.g.*, in German: Natriumchlorid *but* Chlorwasserstoff), but it has not been made consistently, and indeed it seems impossible to introduce this distinction into a consistent system of nomenclature, because the line of demarcation between these two categories is not sharp. In these rules a system of nomenclature has been built on the basis of the endings -ide and -ate, and it should be emphasized that these are intended to be applied both to ionic and covalent compounds. If it is desired to avoid such endings for neutral molecules, names can be given as coördination compounds in accordance with **2.24** and Section **7.**

2.1. Formulas

2.11.—Formulas provide the simplest and clearest method of designating inorganic compounds. They are of particular importance in chemical equations and in descriptions of chemical procedure. However, their general use in text is not recommended, although in some cases a formula, on account of its compactness, may be preferable to a cumbersome and awkward name.

2.12.—The *empirical formula* is formed by juxtaposition of the atomic symbols to give the *simplest possible* formula expressing the stoichiometric composition of the compound in question. The empirical formula may be supplemented by indication of the crystal structure—see Section **8.**

2.13.—For compounds consisting of discrete molecules the *molecular formula, i.e.*, a formula corresponding with the correct molecular weight of the compound, should be used, *e.g.*, S_2Cl_2 and $H_4P_2O_6$ and not SCl and H_2PO_3. When the molecular weight varies with temperature, *etc.*, the simplest possible formula generally may be chosen, *e.g.*, S, P, and NO_2 instead of S_8, P_4, and N_2O_4, unless it is desirable to indicate the molecular complexity.

2.14.—In the *structural formula* the sequence and spatial arrangement of the atoms in a molecule are indicated.

2.15.—In formulas the *electropositive constituent* (cation) should always be placed first, *e.g.*, KCl, $CaSO_4$.

This also applies in Romance languages even though the electropositive constituent is placed last in the *name*, *e.g.*, KCl, chlorure de potassium.

If the compound contains more than one electropositive or more than one electronegative constituent, their sequence is determined by Rules **6.32** and **6.33.**

2.16.—In the case of binary compounds between nonmetals that constituent should be placed first which appears earlier in the sequence: B, Si, C, Sb, As, P, N, H, Te, Se, S, At, I, Br, Cl, O, F.

Examples: NH_3, H_2S, N_4S_4, S_2Cl_2, Cl_2O, OF_2

◆Because N_4S_4 is definitely a nitride, not a sulfide, the committees prefer to write the formula S_4N_4, name it sulfur nitride, and cite it as an exception rather than as an example.

2.161.—For compounds containing three or more elements, however, the sequence should in general follow the order in which the atoms are actually bound in the molecule or ion, *e.g.*, NCS^-, not CNS^-, HOCN (cyanic acid), and HONC (fulminic acid).

Although formulas such as HNO_3, $HClO_4$, H_2SO_4, do not agree with this rule and HNO_3 does not even follow the main rule in **2.16**, the Commission does not at this time wish to break the old custom of putting the central atom immediately after the hydrogen atom in such cases (*cf.* Section **5**). The formula for hypochlorous acid may be written HOCl or HClO.

2.17.—In intermetallic compounds the constituents should be placed in the order

Fr, Cs, Rb, K, Na, Li
Ra, Ba, Sr, Ca, Mg, Be
103, No, Md, Fm, Es, Cf, Bk, Cm, Am, Pu, Np, U, Pa, Th, Ac, Lu–La, Y, Sc
Hf, Zr, Ti
Ta, Nb, V
W, Mo, Cr
Re, Tc, Mn
Pt, Ir, Os, Pd, Rh, Ru, Ni, Co, Fe
Au, Ag, Cu
Hg, Cd, Zn
Tl, In, Ga, Al
Pb, Sn, Ge
Bi, Sb
Po

Nonmetals (except Sb) in the order given in **2.16.**

Deviations from this order may be allowed, *e.g.*, when compounds with analogous structures are compared (AgZn and AgMg).

2.18.—The number of identical atoms or atomic groups in a formula is indicated by means of Arabic numerals, placed below and to the right of the symbol or symbols in parentheses ( ) or brackets [ ] to which they refer. Water of crystallization and similar loosely bound molecules, however, are designated by means of Arabic numerals before their formulas.

Examples: $CaCl_2$ not $CaCl^2$
$[Co(NH_3)_6]Cl_3$ not $[Co6NH_3]Cl_3$
$[Co(NH_3)_6]_2(SO_4)_3$
$Na_2SO_4.10H_2O$

2.19.—The prefixes *cis, trans, sym, asym* may be used in their usual senses. The prefixes may be connected with the formula by a hyphen and it is recommended that they be italicized.
Example: *cis*-$[PtCl_2(NH_3)_2]$

2.2. Systematic Names

Systematic names of compounds are formed by indicating the constituents and their proportions according to the following rules. (For the order of the constituents see also the later sections.)

2.21.—The name of the *electropositive constituent* (or that treated as such according to **2.16**) will not be modified (see, however, **2.2531**).

In Germanic languages the electropositive constituent is placed first, but in Romance languages it is customary to place the electronegative constituent first.

2.22.—If the *electronegative constituent* is monatomic its name is modified to end in -ide. For binary compounds of the nonmetals the name of the element standing later in the sequence in **2.16** is modified to end in -ide.

Examples: Sodium chloride, calcium sulfide, lithium nitride, arsenic selenide, calcium phosphides, nickel arsenide, aluminum borides, iron carbides, boron hydrides, phosphorus hydrides, hydrogen chloride, hydrogen sulfide, silicon carbide, carbon disulfide, sulfur hexafluoride, chlorine dioxide, oxygen difluoride.

Certain polyatomic groups are also given the ending -ide—see **3.22**.

In the Romance languages the endings -ure, -uro, and -eto are used instead of -ide. In some languages the word *oxyde* is used, whereas the ending -ide is used in the names of other binary compounds; it is recommended that the ending -ide be universally adopted in these languages.

◆Nitrogen sulfide has been taken out of the examples. *Cf.* comment at 2.16.

2.23.—If the electronegative constituent is polyatomic it should be designated by the termination -ate. In certain exceptional cases the terminations -ide and -ite are used—see **3.22**.

2.24.—In inorganic compounds it is generally possible in a polyatomic group to indicate a *characteristic atom* (as in ClO^-) or a *central atom* (as in ICl_4^-). Such a polyatomic group is designated a *complex*, and the atoms, radicals, or molecules bound to the characteristic or central atom are termed *ligands*.

In this case the name of a negatively charged complex should be formed from the name of the characteristic or central element (as indicated in **1.12**) modified to end in -ate.

Anionic ligands are indicated by the termination -o. Further details concerning the designation of ligands, the definition of "central atom," *etc.*, appear in Section **7**.

Although the terms sulfate, phosphate, *etc.*, were originally the names of the anions of particular oxo acids, the names sulfate, phosphate, *etc.*, should now designate quite generally a negative group containing sulfur or phosphorus, respectively, as the central atom, irrespective of its oxidation state (the designation of the oxidation state is discussed in later rules) and the number and nature of the ligands. The complex is indicated by brackets [ ], but this is not always necessary.

Examples:

$Na_2[SO_4]$	sodium tetraoxosulfate	$Na_3[PS_4]$	sodium tetrathiophosphate
$Na_2[SO_3]$	sodium trioxosulfate	$Na[PCl_6]$	sodium hexachlorophosphate
$Na_2[S_2O_3]$	sodium trioxothiosulfate	$K[PO_2F_2]$	potassium dioxodifluorophosphate
$Na[SO_3F]$	sodium trioxofluorosulfate	$K[POCl_2(NH)]$	potassium oxodichloroimidophosphate
$Na_3[PO_4]$	sodium tetraoxophosphate		

In many cases these names may be abbreviated, *e.g.*, sodium sulfate, sodium thiosulfate (see **2.26**), and in other cases trivial names may be used (*cf.* **2.3**, **3.224**, and Section **5**). It should be pointed out, however, that the principle is quite generally applicable, to compounds containing organic ligands also, and its use is recommended in all cases where trivial names do not exist.

The coördination principle applied in this rule may also be applied to complexes which are positive or neutral (*cf.* **3.1** and Section **7**). However, neutral complexes which are as a rule considered as binary compounds are given names according to **2.22**, **2.16**. Thus, SO_3, sulfur trioxide, not trioxosulfur.

◆In the examples it would seem that full coördination-type names should be given, *e.g.*, either sodium tetraoxosulfate (VI) or disodium tetraoxosulfate. *Cf.* 7.32 and comment at 7.312.

2.25.—Indication of the Proportions of the Constituents.

2.251.—The *stoichiometric proportions* may be denoted by means of Greek numerical prefixes (mono, di, tri, tetra, penta, hexa, hepta, octa, ennea, deca, hendeca, and dodeca) preceding without hyphen the names of the elements to which they refer. It may be necessary in some languages to supplement these numerals with hemi ($^1/_2$) and the Latin sesqui ($^3/_2$).

The prefix mono may generally be omitted. Beyond 12, Greek prefixes are replaced by Arabic numerals (with or without hyphen according to the custom of the language), because they are more readily understood.

This sytem is applicable to all types of compounds and is especially suitable for binary compounds of the nonmetals.

When it is required to indicate the number of entire groups of atoms, particularly when the name includes a numerical prefix with a different significance, the multiplicative numerals (Latin bis, Greek tris, tetrakis, *etc.*) are used and the whole group to which they refer may be placed in parentheses if necessary.

Examples:

N_2O	dinitrogen oxide	Fe_3O_4	triiron tetraoxide
NO_2	nitrogen dioxide	U_3O_8	triuranium octaoxide
N_2O_4	dinitrogen tetraoxide	MnO_2	manganese dioxide
N_2S_5	dinitrogen pentasulfide	$Ca_3[PO_4]_2$	tricalcium diorthophosphate
S_2Cl_2	disulfur dichloride	$Ca[PCl_6]_2$	calcium bis(hexachlorophosphate)

In indexes it may be convenient to italicize a numerical prefix at the beginning of the name and connect it to the rest of the name with a hyphen, but this is not desirable in text, *e.g.*, *tri*-Uranium octaoxide.

Since the degree of polymerization of many substances varies with temperature, state of aggregation, *etc.*, the name to be used should normally be based upon the simplest possible formula of the substance except when it is required specifically to draw attention to the degree of polymerization.

Example: The name nitrogen dioxide may be used for the equilibrium mixture of NO_2 and N_2O_4. Dinitrogen tetraoxide means specifically N_2O_4.

◆In accordance with the organic nomenclature rules and well-established practice, it is recommended that "or Latin" be inserted between "Greek" and "numerical prefixes" in the first sentence and that "nona" replace "ennea," and "undeca" replace "hendeca."

Extreme caution is advised in the omission of numerical prefixes, including mono (*cf.* second set of examples in 5.23), because of the frequent use of names such as chloroplatinate (*cf.* 2.26 and the last sentence in 5.24).

2.252.—The proportions of the constituents also may be indicated indirectly by *Stock's system*, that is, by Roman numerals representing the oxidation number or stoichiometric valence of the element, placed in parentheses immediately following the name. For zero the Arabic 0 will be used. When used in conjunction with symbols the Roman numeral may be placed above and to the right.

The Stock notation can be applied to both cations and anions, but preferably should *not* be applied to compounds between nonmetals.

In employing the Stock notation, use of the Latin names of the elements (or Latin roots) is considered advantageous.

Examples:

$FeCl_2$	iron(II) chloride or ferrum(II) chloride
$FeCl_3$	iron(III) chloride or ferrum(III) chloride
MnO_2	manganese(IV) oxide
BaO_2	barium(II) peroxide
$Pb^{II}_2Pb^{IV}O_4$	dilead(II) lead(IV) oxide or trilead tetraoxide
$K_4[Ni(CN)_4]$	potassium tetracyanonicollate(0)
$K_4[Fe(CN)_6]$	potassium hexacyanoferrate(II)
$Na_2[Fe(CO)_4]$	sodium tetracarbonylferrate(—II)

◆While the committees favor the extended use of the Stock notation, they suggest that in some cases the system of Ewens and Bassett (designation of the aggregate charge of a complex ion by an Arabic numeral in parentheses following the name, similar to the use as superior notations with formulas) is advantageous and should be allowed as an alternate (*cf.* 3.17 and comment at 7.323). Mixed use of the two systems, while not desirable in any one context, does not affect indexing and should not lead to confusion. See comment at 1.12.

2.253.—The following systems are in use but are not recommended:

2.2531.—The system of indicating valence by means of the suffixes *-ous* and *-ic* added to the root of the name of the cation may be retained for elements exhibiting not more than two valences.

2.2532.—*"Functional"* nomenclature (such as "nitric anhydride" for N_2O_5) is not recommended apart from the name *acid* to designate the acid function (Section **5**).

◆Apparently there is no objection to acid anhydride as a class name (*cf.* 5.32). Other functional derivatives of acids are named as such in the Rules (5.3).

2.26.—In systematic names it is not always necessary to indicate stoichiometric proportions. In many instances it is permissible to omit the numbers of atoms, oxidation numbers, *etc.*, when they are not required in the particular circumstances. For instance, these indications are not generally necessary with elements of essentially constant valence.

Examples:

sodium sulfate instead of sodium tetraoxosulfate
aluminum sulfate instead of aluminum(III) sulfate
potassium chloroplatinate(IV) instead of potassium hexachloroplatinate(IV)
potassium cyanoferrate(III) instead of potassium hexacyanoferrate(III)
phosphorus pentaoxide instead of diphosphorus pentaoxide

2.3. Trivial Names

Certain well-established trivial names for oxo acids (Section **5**) and for hydrogen compounds (water, ammonia, hydrazine) are still acceptable. For some other hydrogen compounds these names are approved:

B_2H_6	diboran	PH_3	phosphine	SbH_3	stibine	P_2H_4	diphosphine
SiH_4	silane	AsH_3	arsine	Si_2H_6	disilane, *etc.*	As_2H_4	diarsine

In some languages names of the type "Chlorwasserstoff" are in use and may be retained if national nomenclature committees so wish.

Purely trivial names, free from false scientific implications, such as soda, Chile saltpeter, quicklime, are harmless in industrial and popular literature; but old incorrect scientific names such as sulfate of magnesia, Natronhydrat, sodium muriate, carbonate of lime, should be avoided under all circumstances, and they should be eliminated from technical and patent literature.

◆For BH_3 (omitted in the Rules) borane rather than the previously used borine has been recommended by the Advisory Committee on the Nomenclature of Organic Boron Compounds of the ACS in a report not yet published.

Because soda is an ambiguous term, it is suggested that it be replaced by soda ash.

3. NAMES FOR IONS AND RADICALS

3.1. Cations

3.11.—Monatomic cations should be named like the corresponding element, without change or suffix, except as provided by **2.2531**.

Examples:

Cu^+ the copper(I) ion Cu^{2+} the copper(II) ion I^+ the iodine cation

◆For I^+, iodide(I) cation is more consistent with recommended practice. *Cf.* 3.21.

3.12.—The preceding principle should apply also to polyatomic cations corresponding to radicals for which special names are given in **3.32**, *i.e.*, these names should be used without change or suffix.

Examples: NO^+ the nitrosyl cation NO_2^+ the nitryl cation

◆Polyatomic here and in 3.13, 3.14, 3.223, 3.32, and 5.2 seems to be limited to more than one *kind* of atom, and hence heteratomic would be a more precise term. It is agreed that nitryl and not nitronium should be used in all cases (*cf.* 3.151).

3.13.—Polyatomic cations formed from monatomic cations by the addition of other ions or neutral atoms or molecules (ligands) will be regarded as complex and will be named according to the rules given in Section **7**.

Examples:

$[Al(H_2O)_6]^{3+}$ the hexaaquoaluminum ion $[CoCl(NH_3)_5]^{2+}$ the chloropentamminecobalt ion

For some important polyatomic cations which fall in this section, radical names given in **3.32** may be used alternatively, *e.g.*, for UO_2^{2+} the name uranyl(VI) ion in place of dioxouranium(VI) ion.

3.14.—Names for polyatomic cations derived by addition of protons to monatomic anions are formed by adding the ending -onium to the root of the name of the anion element.

Examples: phosphonium, arsonium, stibonium, oxonium, sulfonium, selenonium, telluronium, and iodonium ions.

Organic ions derived by substitution in these parent cations should be named as such, whether the parent itself is a known compound or not: for example $(CH_3)_4Sb^+$, the tetramethylstibonium ion.

The ion H_3O^+, which is in fact the monohydrated proton, is to be known as the oxonium ion when it is believed to have this constitution, as for example in $H_2O^+ClO_4^-$, oxonium perchlorate. The widely used term hydronium should be kept for the cases where it is wished to denote an indefinite degree of hydration of the proton, as, for example, in aqueous solution. If, however, the hydration is of no particular importance to the matter under consideration, the simpler term hydrogen ion may be used. The latter also may be used for the indefinitely solvated proton in nonaqueous solvents; but definite ions such as $CH_3OH_2^+$ and $(CH_3)_2OH^+$ should be named as derivatives of the oxonium ion, *i.e.*, as methyl- and dimethyloxonium ions, respectively.

◆The committees concur in oxonium for the ion H_3O^+, but see little reason for encouraging retention of the term hydronium ion because hydrogen ion adequately designates an indeterminate degree of hydration.

3.15.—Ions from Nitrogen Bases.

3.151.—The name ammonium for the ion NH_4^+ does not conform to **3.14**, but should be retained. This decision does *not* release the word nitronium for other uses: this would lead to inconsistencies when the rules are applied to other elements.

3.152.—Substituted ammonium ions derived from nitrogen bases with names ending in -amine will receive names formed by changing -amine to -ammonium. For example, $HONH_3^+$, the hydroxylammonium ion.

3.153.—When the nitrogen base is known by a name ending otherwise than in -amine, the cation name is to be formed by adding the ending -ium to the name of the base (if necessary omitting a final -e or other vowel).

Examples: hydrazinium, anilinium, glycinium, pyridinium, guanidinium, imidazolium.

The names uronium and thiouronium, though inconsistent with this rule, may be retained.

3.16.—Cations formed by adding protons to nonnitrogenous bases may also be given names formed by adding -ium to the name of the compound to which the proton is added.

Examples: dioxanium, acetonium.

In the case of cations formed by adding protons to acids, however, their names are to be formed by adding the word acidium to the name of the corresponding anion, and not that of the acid itself. For example, $H_2NO_3^+$, the nitrate acidium ion; $H_2NO_2^+$, the nitrite acidium ion; and $CH_3COOH_2^+$, the acetate acidium ion. Note, however, that when the anion of the acid is monatomic **3.14** will apply; for example, FH_2^+ is the fluoronium ion.

◆In accord with present practice, nitric acidium ion, *etc.*, are preferred to nitrate acidium ion, *etc.* $CH_3COOH_2^+$ is organic.

3.17.—Where more than one ion is derived from one base, as, for example, $N_2H_5^+$ and $N_2H_6^{2+}$, their charges may be indicated in their names as the hydrazinium(1+) and the hydrazinium(2+) ion, respectively.

◆*Cf.* comment at 2.252 and the use of Stock notation with ions or radicals in 3.13 and 3.32.

3.2. Anions

3.21.—The names for monatomic anions shall consist of the name (sometimes abbreviated) of the element, with the termination -ide. Thus

H^-	hydride ion	Br^-	bromide ion	Se^{2-}	selenide ion	As^{3-}	arsenide ion
D^-	deuteride ion	I^-	iodide ion	Te^{2-}	telluride ion	Sb^{3-}	antimonide ion
F^-	fluoride ion	O^{2-}	oxide ion	N^{3-}	nitride ion	C^{4-}	carbide ion
Cl^-	chloride ion	S^{2-}	sulfide ion	P^{3-}	phosphide ion	Si^{4-}	silicide ion
				B^{3-}	boride ion		

Expressions of the type "chlorine ion" are used particularly in connection with crystal structure work and spectroscopy; the Commission recommends that whenever the charge corresponds with that indicated above, the termination -ide should be used.

◆*Cf.* comments at 1.15 and 1.32 regarding ^2H and D.

3.22. Polyatomic Anions.

3.221.—Certain polyatomic anions have names ending in -ide. These are

OH^-	hydroxide ion	I_3^-	triiodide ion	$NHOH^-$	hydroxylamide ion
O_2^{2-}	peroxide ion	HF_2^-	hydrogen difluoride ion	$N_2H_3^-$	hydrazide ion
O_2^-	hyperoxide ion	N_3^-	azide ion	CN^-	cyanide ion
O_3^-	ozonide ion	NH^{2-}	imide ion	C_2^{2-}	acetylide ion
S_2^{2-}	disulfide ion	NH_2^-	amide ion		

Names for other polysulfide, polyhalide, *etc.*, ions may be formed in analogous manner. The OH^- ion should not be called the hydroxyl ion. The name hydroxyl is reserved for the OH group when neutral or positively charged, whether free or as a substituent (*cf.* **3.12** and **3.32**).

◆Superoxide is well established in English for O_2^- and no advantage is seen in changing to hyperoxide.

3.222.—Ions such as SH^- and O_2H^- will be called the hydrogen sulfide ion and the hydrogen peroxide ion, respectively. This agrees with **6.2**, and names such as hydrosulfide are not needed.

◆*Cf.* comment at 6.2. All "fused" names (as hydrogensulfide here and methylisocyanide in 5.33) in the original version have been written as two words in this version. For a rule on the written form of the names of compounds see *J. Chem. Education*, 8, 1336–8 (1931)

3.223.—The names for other polyatomic anions shall consist of the name of the central atom with the termination -ate, which is used quite generally for complex anions. Atoms and groups attached to the central atom shall generally be treated as ligands in a complex (*cf.* **2.24** and Section **7**) as, for example, $[Sb(OH)_6]^-$, the hexahydroxoantimonate(V) ion.

This applies also when the exact composition of the anion is not known; *e.g.*, by solution of aluminum hydroxide or zinc hydroxide in sodium hydroxide, aluminate and zincate ions are formed.

3.224.—It is quite practicable to treat oxygen in the same manner as other ligands (**2.24**), but it has long been customary to ignore the name of this element altogether in anions and to indicate its presence and proportion by means of a series of prefixes (hypo-, per-, *etc.*, see Section **5**) and sometimes also by the suffix -ite in place of -ate.

The termination -ite has been used to denote a lower oxidation state and may be retained in trivial names in these cases

NO_2^-	nitrite	$PH_2O_2^-$	hypophosphite	$S_2O_2^{2-}$	thiosulfite
$N_2O_2^{2-}$	hyponitrite	AsO_3^{3-}	arsenite	SeO_3^{2-}	selenite
NOO_2^-	peroxonitrite	SO_3^{2-}	sulfite	ClO_2^-	chlorite
PHO_3^{2-}	phosphite	$S_2O_5^{2-}$	disulfite (pyrosulfite)	ClO^-	hypochlorite
$P_2H_2O_5^{2-}$	diphosphite (pyrophosphite)	$S_2O_4^{2-}$	dithionite		

(and correspondingly for the other halogens)

The Commission does not recommend the use of any such names other than those listed. A number of other names ending in -ite have been used, *e.g.*, antimonite, tellurite, stannite, plumbite, ferrite, manganite, but in many cases such compounds are known in the solid state to be double oxides and are to be treated as such (*cf.* **6.5**), *e.g.*, $Cu(CrO_2)_2$ copper(II) chromium(III) oxide, not copper chromite. Where there is reason to believe that a definite salt with a discrete anion exists, the name is formed in accordance with **2.24**. By dissolving, for example, Sb_2O_3, SnO, or PbO in sodium hydroxide an antimonate(III), a stannate(II), or a plumbate(II) is formed in the solution.

Concerning the use of prefixes hypo-, per-, *etc.*, see the list of acids (table in **5.214**). For all new compounds and even for the less common ones listed in the table in **3.224** or derived from the acids listed in the table in **5.214**, it is preferable to use the system given in **2.24** and in Sections **5** and **7**.

◆For phosphite names see comment at 6.2.

3.3. Radicals

3.31.—A radical is here regarded as a group of atoms which occurs repeatedly in a number of different compounds. Sometimes the same radical fulfils different functions in different cases, and accordingly different names often have been assigned to the same group. The Commission considers it desirable to reduce this diversity and recommends that formulas or systematic names be used to denote all new radicals, instead of introducing new trivial names. The list of names for ions and radicals on page B-169 gives an extensive selection of radical names at present in use in inorganic chemistry.

◆The list of names for ions and radicals following the Rules is very useful and can be made more so by additions (as of dithio, nitrilo, and azido in the last column) and by greater attempt at uniformity with organic usage. Some of the terms (as nitride and amide) listed as anions are used also of covalent compounds. A single atom may function like a radical as defined above and may be named similarly, as chloro and oxo.

3.32.—Certain radicals containing oxygen or other chalcogens have special names ending in -yl, and the Commission approves the provisional retention of

HO	hydroxyl	S_2O_5	pyrosulfuryl	PO	phosphoryl	ClO_2	chloryl
CO	carbonyl	SeO	seleninyl	VO	vanadyl	ClO_3	perchloryl (and similarly for other halogens)
NO	nitrosyl	SeO_2	selenonyl	PuO_2	plutonyl (similarly for other actinide elements)		
SO	sulfinyl (thionyl)	CrO_2	chromyl				
SO_2	sulfonyl (sulfuryl)	UO_2	uranyl				
		NpO_2	neptunyl				
		NO_2	nitryl[1]	ClO	chlorosyl		

[1]The name nitroxyl should not be used for this group since the name nitroxylic acid has been used for H_2NO_2. Although the word nitryl is firmly established in English, nitroyl may be a better model for many other languages.

Names such as the above should be used only to designate compounds containing these discrete groups. The use of thionyl and sulfuryl should be restricted to the halides. Names such as bismuthyl and antimonyl are not approved because the compounds do not contain BiO and SbO groups, respectively; such compounds are to be designated as oxide halides (**6.4**).

Radicals analogous to the above containing other chalcogens in place of oxygen are named by adding the prefixes thio-, seleno-, *etc.*

Examples:

PS thiophosphoryl CSe selenocarbonyl

In cases where radicals may have different valences, the oxidation number of the characteristic element should be indicated by means of the Stock notation. For example, the uranyl group UO_2 may refer either to the ion UO_2^{2+} or to the ion UO_2^{+}; these can be distinguished as uranyl(VI) and uranyl(V), respectively. In like manner, VO may be vanadyl(V), vanadyl(IV), and vanadyl(III).

These polyatomic radicals always are treated as forming the positive part of the compound.

Examples:

$COCl_2$	carbonyl chloride	$NO_2HS_2O_7$	nitryl hydrogen disulfate
NOS	nitrosyl sulfide	S_2O_5ClF	pyrosulfuryl chloride fluoride
PON	phosphoryl nitride	$SO_2(N_3)_2$	sulfonyl azide
$PSCl_3$	thiophosphoryl chloride	SO_2NH	sulfonyl imide
POCl	phosphoryl(III) chloride	IO_2F	iodyl fluoride

By using the same radical names regardless of unknown or controversial polarity relationships, names can be formed without entering into any controversy. Thus, for example, the compounds NOCl and $NOClO_4$ are quite unambiguously denoted by the names nitrosyl chloride and nitrosyl perchlorate, respectively.

◆Caution is urged in the use of some of these radical names: Vanadyl, for example, has been used for VO_2 as well as for VO (*cf.* also the naming of $VOSO_4$ in 6.42). Most of these radical names (except hydroxyl and thionyl) can be regarded as derived from the names of acids which have lost all of their hydroxyls (analogous to -yl or -oyl organic acid radical names) by the use of -yl and -osyl for radicals from -ic and -ous acids, respectively; this is implied in the footnote about nitroxyl. The use of the Stock notation in only one example (phosphoryl(III) chloride) seems confusing. It might be clearer to indicate stoichiometric proportions, *e.g.*, phosphoryl (mono)chloride, thiophosphoryl trichloride (*cf.* phosphoryl triamide in 5.34) or to use phosphorosyl for phosphoryl(III).

The restriction of the use of thionyl and sulfuryl to the halides was agreed upon at a joint meeting of the inorganic and organic nomenclature commissions of the IUPAC in 1951.

3.33.—It should be noted that the same radical may have different names in inorganic and organic chemistry. To draw attention to such differences the prefix names of radicals as substituents in organic compounds have been listed together with the inorganic names in the list of names printed at the end of the Rules. Names of purely organic compounds, of which many are important in the chemistry of coördination compounds (Section 7), should agree with the nomenclature of organic chemistry.

Organic chemical nomenclature is to a large extent based on the principle of substitution, *i.e.*, replacement of hydrogen atoms by other atoms or groups. Such "substitutive names" are extremely rare in inorganic chemistry; they are used, *e.g.*, in the following cases: NH_2Cl is called chloramine, and $NHCl_2$ dichloramine. These names may be retained in the absence of better terms. Other substitutive names (derived from "sulfonic acid" as a name for HSO_3H) are fluoro- and chlorosulfonic acid, aminosulfonic acid, iminodisulfonic acid, and nitrilotrisulfonic acid. These names should preferably be replaced by the following

FSO_3H	fluorosulfuric acid	$NH(SO_3H)_2$	imidodisulfuric acid
$ClSO_3H$	chlorosulfuric acid	$N(SO_3H)_3$	nitridotrisulfuric acid
NH_2SO_3H	amidosulfuric acid		

Names such as chlorosulfuric acid and amidosulfuric acid might be considered to be substitutive names derived by substitution of *hydroxyl* groups in sulfuric acid. From a more fundamental point of view, however (see **2.24**), such names are formed by adding hydroxyl, amide, imide, *etc.*, groups together with oxygen atoms to a sulfur atom, "sulfuric acid" in this connection standing as an abbreviation for "trioxosulfuric acid."

Another organic-chemical type of nomenclature, the formation of "conjunctive names," is also met in only a few cases in inorganic chemistry, *e.g.*, the hydrazine- and hydroxylaminesulfonic acids. According to the principles of inorganic chemical nomenclature these compounds should be called hydrazido- and hydroxylamidosulfuric acid.

◆These are not true "conjunctive names" since sulfonic acid is not a compound. For the naming of partial amides *cf.* also 5.34.

4. CRYSTALLINE PHASES OF VARIABLE COMPOSITION

Isomorphous replacement, interstitial solutions, intermetallic compounds, and other nonstoichiometric compounds (berthollides)

4.1.—If an intermediate crystalline phase occurs in a two-component (or more complex) system, it may obey the law of constant composition very closely, as in the case of sodium chloride, or it may be capable of varying in composition over an appreciable range, as occurs for example with FeS. A substance showing such a variation is called a *berthollide*.

In connection with the berthollides the concept of a characteristic or ideal composition is frequently used. A unique definition of this concept seems to be lacking. In one case it may be necessary to use a definition based upon lattice geometry and in another to base it on the ratio of valence electrons to atoms. Sometimes one can state several characteristic compositions, and at other times it is impossible to say whether a phase corresponds to a characteristic composition or not.

In spite of these difficulties it seems that the concept of a characteristic composition can be used in its present undefined form for establishing a system of notation for phases of variable composition. It also seems possible to use the concept even if the characteristic composition is not included in the known homogeneity range of the phase.

4.2.—For the present, mainly formulas should be used for berthollides and solid solutions, since strictly logical names tend to become inconveniently cumbersome. The latter should be used only when unavoidable (*e.g.*, for indexing), and may be written in the style of iron(II) sulfide (iron-deficient); molybdenum dicarbide (excess carbon), or the like. Mineralogical names should be used only to designate actual minerals and not to define chemical composition; thus the name calcite refers to a particular mineral (contrasted with other minerals of similar composition) and is not a term for the chemical compound whose composition is properly expressed by the name calcium carbonate. (The mineral name may, however, be used to indicate the structure type—see **6.52.**)

4.3.—A general notation for the berthollides, which can be used even when the mechanism of the variation in composition is unknown, is to put the sign $\sim$ (read as *circa*) before the formula. (In special cases it may also be printed above the formula.)

Examples: $\sim$FeS, $\widetilde{\mathrm{CuZn}}$

The direction of the deviation may be indicated when required:

$\sim$FeS (iron-deficient); $\sim MoC_2$ (excess carbon)

4.4.—For a phase where the variable composition is solely or partially caused by replacement, atoms or atomic groups which replace each other are separated by a comma and placed together between parentheses.

If possible the formula ought to be written so that the limits of the homogeneity range are represented when one or other of the two atoms or groups is lacking. For example the symbol (Ni,Cu) denotes the complete range from pure Ni to pure Cu; likewise K(Br,Cl) comprises the range from pure KBr to pure KCl. If only part of the homogeneity range is referred to, the major constituent should be placed first.

Substitution accompanied by the appearance of vacant positions (combination of substitutional and interstitial solution) receives an analogous notation. For example, $(Li_2,Mg)Cl_2$ denotes the homogeneous phase from LiCl to $MgCl_2$ where the anion lattice structure remains the same but one vacant cation position appears for every substitution of $2Li^+$ by Mg^{2+}.

The formula $(Mg_3,Al_2)Al_6O_{12}$ represents the homogeneous phase from the spinel $MgAl_2O_4$ (= $Mg_3Al_6O_{12}$) to the spinel form of Al_2O_3 (= $Al_2Al_6O_{12}$).

The solid solutions between CaF_2 and YF_3, where cation substitution is accompanied by interstitial addition of F^-, would be represented by the formula $(Ca,YF)F_2$. It is important to note that this formula is based purely on considerations of composition, and it does not imply that YF^{2+} takes over the actual physical position of Ca^{2+}. On the same basis a notation for the plagioclases would be $(NaSi,CaAl)Si_2AlO_8$.

4.5.—A still more complete notation, which should always be used in more complex cases, may be constructed by indicating in a formula the variables that define the composition. Thus, a phase involving simple substitution may be written A_xB_{1-x}.

Examples: Ni_xCu_{1-x} and KBr_xCl_{1-x}

This shows immediately that the total number of atoms in the lattice is constant. Combined substitutional and interstitial or subtractive solution can be shown in an analogous way. The commas and parentheses called for in **4.4** are not required in this case.

For example, the homogeneous phase between LiCl and $MgCl_2$ becomes $Li_{2x}Mg_{1-x}Cl_2$ and the phase between $MgAl_2O_4$ and Al_2O_3 can be written $Mg_{3x}Al_{2(1-x)}Al_6O_{12}$, which shows that it cannot contain more Mg than that corresponding to $MgAl_2O_4$ ($x = 1$). The other examples given in **4.4** will be given the formulas $Ca_xY_{1-x}F_{3-x}$ and $Na_xCa_{1-x}Si_{2+x}Al_{2-x}O_8$. In the case of the γ-phase of the Ag–Cd system, which has the characteristic formula Ag_5Cd_8, the Ag and Cd atoms can replace one another to some extent and the notation would be $Ag_{5\pm x}Cd_{8\mp x}$.

Further examples:

$Fe_{1-x}Sb$ $Fe_{1-x}O$ $Fe_{1-x}S$ $Cu_{2-x}O$ $Na_{1-x}WO_3$ (sodium tungsten bronzes)

For $x = 0$ each of these formulas corresponds to a characteristic composition. If it is desired to show that the variable denoted by x can attain only small values, this may be done by substituting ϵ for x.

Likewise a solid solution of hydrogen in palladium can be written as PdH_x, and a phase of the composition M which has dissolved a variable amount of water can be written $M(H_2O)_x$.

When this notation is used, a particular composition can be indicated by stating the actual value of the variable x. Probably the best way of doing this is to put the value in parentheses after the general formula. For example, $Li_{4-x}Fe_{3x}Ti_{2(1-x)}O_6$ ($x = 0.35$). If it is desired to introduce the value of x into the formula itself, the mechanism of solution is more clearly understood if one writes $Li_{4-0.35}Fe_{3\times0.35}Ti_{2(1-0.35)}O_6$ instead of $Li_{3.65}Fe_{1.05}Ti_{1.30}O_6$.

5. ACIDS

Many of the compounds which now according to some definitions are called acids do not fall into the classical province of acids. In other parts of inorganic chemistry functional names are disappearing and it would have been most satisfactory to abolish them also for those compounds generally called acids. Names for these acids may be derived from the names of the anions as in Section 2, *e.g.*, hydrogen sulfate instead of sulfuric acid. The nomenclature of acids has, however, a long history of established custom, and it appears impossible to systematize acid names without drastic alteration of the accepted names of many important and well-known substances.

The present rules are aimed at preserving the more useful of the older names while attempting to guide further development along directions which should allow new compounds to be named in a more systematic manner.

5.1. Binary and Pseudobinary Acids

Acids giving rise to the -ide anions defined by **3.21** and **3.221** will be named as binary and pseudobinary compounds of hydrogen, *e.g.*, hydrogen chloride, hydrogen sulfide, hydrogen cyanide.

For the compound HN_3 the name hydrogen azide is recommended in preference to hydrazoic acid.

5.2. Acids Derived from Polyatomic Anions

Acids giving rise to anions bearing names ending in -ate or in -ite may also be treated as in **5.1**, but names more in accordance with custom are formed by using the terminations -ic acid and -ous acid corresponding with the anion terminations -ate and -ite, respectively. Thus chloric acid corresponds to chlorate, sulfuric acid to sulfate, and phosphorous acid to phosphite.

This nomenclature may also be used for less common acids, *e.g.*, hexacyanoferric acids correspond to hexacyanoferrate ions. In such cases, however, systematic names of the type hydrogen hexacyanoferrate are preferable.

Most of the common acids are oxo acids, *i.e.*, they contain only oxygen atoms bound to the characteristic atom. It is a long-established custom not to indicate these oxygen atoms. It is mainly for these acids that long-established names will have to be retained. Most other acids may be considered as coördination compounds and be named as such.

◆Polyatomic means heteratomic here, as opposed to pseudobinary. *Cf.* comment at 3.12.

5.21. Oxo Acids.—For the oxo acids the ous–ic notation to distinguish between different oxidation states is applied in many cases. The -ous acid names are restricted to acids corresponding to the -ite anions listed in the table in **3.224**.

Further distinction between different acids with the same characteristic element is in some cases effected by means of prefixes. This notation should not be extended beyond the cases listed below.

5.211.—The prefix hypo- is used to denote a lower oxidation state, and may be retained in these cases

$H_4B_2O_4$	hypoboric acid	HPH_2O_2	hypophosphorous acid
$H_2N_2O_2$	hyponitrous acid	HOCl	hypochlorous acid (and similarly for the other halogens)
$H_4P_2O_6$	hypophosphoric acid		

5.212.—The prefix per- is used to designate a higher oxidation state and may be retained for $HClO_4$, perchloric acid, and similarly for the other elements in Group VII.

The prefix per- should not be confused with the prefix peroxo- (see **5.22**).

5.213.—The prefixes ortho- and meta- have been used to distinguish acids differing in "water content." These names are approved

H_3BO_3	orthoboric acid	H_5IO_6	orthoperiodic acid	$(H_2SiO_3)_n$	metasilicic acids
H_4SiO_4	orthosilicic acid	H_6TeO_6	orthotelluric acid	$(HPO_3)_n$	metaphosphoric acids
H_3PO_4	orthophosphoric acid	$(HBO_2)_n$	metaboric acids		

For the acids derived by removing water from orthoperiodic or orthotelluric acid, the systematic names should be used, *e.g.*, HIO_4 tetraoxoiodic(VII) acid.

The prefix pyro- has been used to designate an acid formed from two molecules of an ortho acid minus one molecule of water. Such acids can now generally be regarded as the simplest cases of isopoly acids (*cf.* **7.5**). The prefix pyro- may be retained for pyrosulfurous and pyrosulfuric acids and for pyrophosphorous and pyrophosphoric acids, although in these cases also the prefix di- is preferable.

◆The use of orthoperiodic acid and orthotelluric acid is approved, but the question of names for HIO_4, *etc.*, needs further study because of confusion in the literature.

5.214.—The accompanying Table II contains the accepted names of the oxo acids (whether known in the free state or not) and some of their thio and peroxo derivatives (**5.22** and **5.23**).

For the less common of these acids systematic names would seem preferable, for example

H_2MnO_4 manganic(VI) acid, to distinguish it from H_3MnO_4, manganic(V) acid

$HReO_4$ tetraoxorhenic(VII) acid, to distinguish it from H_5ReO_5, pentaoxorhenic(VII) acid

H_2ReO_4 tetraoxorhenic(VI) acid, to distinguish it from $HReO_3$, trioxorhenic(V) acid; H_3ReO_4, tetraoxorhenic(V) acid; and $H_4Re_2O_7$, heptaoxodirhenic(V) acid

H_2NO_2 dioxonitric(II) acid instead of nitroxylic acid.

Trivial names should not be given to such acids as HNO, $H_2N_2O_3$, $H_2N_2O_4$, of which salts have been described. These salts are to be designated systematically as oxonitrates(I), trioxodinitrates(II), tetraoxodinitrates(III), respectively.

The names germanic acid, stannic acid, antimonic acid, bismuthic acid, vanadic acid, niobic acid, tantalic acid, telluric acid, molybdic acid, wolframic acid, and uranic acid may be used for substances with indefinite "water content" and degree of polymerization.

◆Unless trivial names clash with good nomenclature practices or are ambiguous, retention of well-established ones or the use of formulas is urged (especially for HNO, $H_2N_2O_3$, *etc.*) until structures are known. Systematic coordination-type names in the case of these nitrogen acids, for example, imply a structure that is ruled out by our present state of knowledge

If hexahydroxoantimonic acid is considered a trivial name, hexahydroxy- might be preferable (*cf.* the systematic name hexahydroxoantimonate(V) ion in 3.223). For the analogous use of peroxo and peroxy, see comment at 5.22.

TABLE II

NAMES FOR OXO ACIDS

H_3BO_3	orthoboric acid or (mono)boric acid	H_2SO_4	sulfuric acid
$(HBO_2)_n$	metaboric acids	$H_2S_2O_7$	disulfuric or pyrosulfuric acid
$(HBO_2)_3$	trimetaboric acid	H_2SO_5	peroxo(mono)sulfuric acid
$H_4B_2O_4$	hypoboric acid	$H_2S_2O_8$	peroxodisulfuric acid
H_2CO_3	carbonic acid	$H_2S_2O_3$	thiosulfuric acid
HOCN	cyanic acid	$H_2S_2O_6$	dithionic acid
HNCO	isocyanic acid	H_2SO_3	sulfurous acid
HONC	fulminic acid	$H_2S_2O_5$	disulfurous or pyrosulfurous acid
H_4SiO_4	orthosilicic acid	$H_2S_2O_2$	thiosulfurous acid
$(H_2SiO_3)_n$	metasilicic acids	$H_2S_2O_4$	dithionous acid
HNO_3	nitric acid	H_2SO_2	sulfoxylic acid
HNO_4	peroxonitric acid	$H_2S_xO_6$ (x = 3,4...)	polythionic acids
HNO_2	nitrous acid	H_2SeO_4	selenic acid
HOONO	peroxonitrous acid	H_2SeO_3	selenious acid
H_2NO_2	nitroxylic acid	H_6TeO_6	(ortho)telluric acid
$H_2N_2O_2$	hyponitrous acid	H_2CrO_4	chromic acid
H_3PO_4	(ortho)phosphoric acid	$H_2Cr_2O_7$	dichromic acid
$H_4P_2O_7$	diphosphoric or pyrophosphoric acid	$HClO_4$	perchloric acid
$H_5P_3O_{10}$	triphosphoric acid	$HClO_3$	chloric acid
$H_{n+2}P_nO_{3n+1}$	polyphosphoric acids	$HClO_2$	chlorous acid
$(HPO_3)_n$	metaphosphoric acids	HClO	hypochlorous acid
$(HPO_3)_3$	trimetaphosphoric acid	$HBrO_3$	bromic acid
$(HPO_3)_4$	tetrametaphosphoric acid	$HBrO_2$	bromous acid
H_3PO_5	peroxo(mono)phosphoric acid	HBrO	hypobromous acid
$H_4P_2O_8$	peroxodiphosphoric acid	H_5IO_6	(ortho)periodic acid
$(HO)_2OP–PO(OH)_2$	hypophosphoric acid.	HIO_3	iodic acid
$(HO)_2P–O–PO(OH)_2$	diphosphoric(III,V) acid	HIO	hypoiodous acid
H_2PHO_3	phosphorous acid	$HMnO_4$	permanganic acid
$H_4P_2O_5$	diphosphorous or pyrophosphorous acid	H_2MnO_4	manganic acid
		$HTcO_4$	pertechnetic acid
HPH_2O_2	hypophosphorous acid	H_2TcO_4	technetic acid
H_3AsO_4	arsenic acid	$HReO_4$	perrhenic acid
H_3AsO_3	arsenious acid	H_2ReO_4	rhenic acid
$HSb(OH)_6$	hexahydroxoantimonic acid		

5.22. Peroxo Acids.—The prefix peroxo, when used in conjunction with the trivial names of acids, indicates substitution of –O– by –O–O– (*cf.* **7.312**).

Examples:	HNO_4	peroxonitric acid	H_2SO_5	peroxosulfuric acid
	H_3PO_5	peroxophosphoric acid	$H_2S_2O_8$	peroxodisulfuric acid
	$H_4P_2O_8$	peroxodiphosphoric acid		

◆Peroxy, as recommended in the 1940 Rules (inorganic), is more acceptable than peroxo to organic chemists. It is not necessary that the use with trivial names conform with the use of peroxo denoting a coördinated ligand; *e.g.*, peroxysulfuric acid or trioxoperoxosulfuric(VI) acid.

5.23. Thio Acids.—Acids derived from oxo acids by replacement of oxygen by sulfur are called *thio acids* (*cf.* **7.312**).

Examples: $H_2S_2O_2$ thiosulfurous acid $H_2S_2O_3$ thiosulfuric acid HSCN thiocyanic acid

When more than one oxygen atom can be replaced by sulfur the number of sulfur atoms generally should be indicated

H_3PO_3S	monothiophosphoric acid	H_3AsS_3	trithioarsenious acid
$H_3PO_2S_2$	dithiophosphoric acid	H_3AsS_4	tetrathioarsenic acid
H_2CS_3	trithiocarbonic acid		

The prefixes seleno- and telluro- may be used in a similar manner.

5.24. Chloro Acids, etc.—Acids containing ligands other than oxygen and sulfur are generally designated according to the rules in Section 7.

Examples:

$HAuCl_4$	hydrogen tetrachloraurate(III) or tetrachloroauric(III) acid
H_2PtCl_4	hydrogen tetrachloroplatinate(II) or tetrachloroplatinic(II) acid
H_2PtCl_6	hydrogen hexachloroplatinate(IV) or hexachloroplatinic(IV) acid
$H_4Fe(CN)_6$	hydrogen hexacyanoferrate(II) or hexacyanoferric(II) acid
$H[PHO_2F]$	hydrogen hydridodioxofluorophosphate or hydridodioxofluorophosphoric acid
HPF_6	hydrogen hexafluorophosphate or hexafluorophosphoric acid
H_2SiF_6	hydrogen hexafluorosilicate or hexafluorosilicic acid
H_2SnCl_6	hydrogen hexachlorostannate(IV) or hexachlorostannic(IV) acid
HBF_4	hydrogen tetrafluoroborate or tetrafluoroboric acid
$H[B(OH)_2F_2]$	hydrogen dihydroxodifluoroborate or dihydroxodifluoroboric acid
$H[B(C_6H_5)_4]$	hydrogen tetraphenylborate or tetraphenylboric acid

It is preferable to use names of the type hydrogen tetrachloroaurate(III).

For some of the more important acids of this type abbreviated names may be used, *e.g.*, chloroplatinic acid, fluorosilicic acid.

◆For the use of hydrido in the fifth example see comment at 7.312.

5.3. Functional Derivatives of Acids

Functional derivatives of acids are compounds formed from acids by substitution of OH and sometimes also O by other groups. In this borderline between organic and inorganic chemistry organic-chemical nomenclature principles prevail.

◆The intention of the statement "organic-chemical nomenclature principles prevail" is not clear, since most of the examples given in the sections immediately following are not named according to organic practice. *Cf.* 3.33.

5.31. Acid Halides.—The names of acid halides are formed from the name of the corresponding acid radical if this has a special name, *e.g.*, sulfuryl chloride, phosphoryl chloride.

In other cases these compounds are named as oxide halides according to rule **6.41**, *e.g.*, MoO_2Cl_2, molybdenum dioxide dichloride.

5.32. Acid Anhydrides.—Anhydrides of inorganic acids generally should be given names as oxides, *e.g.*, N_2O_5 dinitrogen pentaoxide, *not* nitric anhydride or nitric acid anhydride.

5.33. Esters.—Esters of inorganic acids are given names in the same way as the salts, *e.g.*, dimethyl sulfate, diethyl hydrogen phosphate.

If, however, it is desired to specify the constitution of the compound, a name based on the nomenclature for cöordination compounds should be used.

Example:

$(CH_3)_4[Fe(CN)_6]$	tetramethyl hexacyanoferrate(II)
or	or
$[Fe(CN)_2(CH_3NC)_4]$	dicyanotetrakis(methyl isocyanide)iron(II)

◆According to common organic practice for esters (ethers, sulfides, *etc.*) and to the naming of inorganic salts (*e.g.*, sodium sulfate, not disodium sulfate), methyl sulfate would be used instead of dimethyl sulfate. However, no objection is seen to the more specific name. Such names as methyl sulfate are better for alphabetic listing, as in indexes.

5.34. Amides.—The names for amides may be derived from the names of acids by replacing acid by amide, or from the names of the acid radicals.

Examples:

$SO_2(NH_2)_2$	sulfuric diamide or sulfonyl diamide
$PO(NH_2)_3$	phosphoric triamide or phosphoryl triamide

If not all hydroxyl groups of the acid have been replaced by NH_2 groups, names ending in -amidic acid may be used: this is an alternative to naming the compounds as complexes.

Examples:

NH_2SO_3H	amidosulfuric acid or sulfamidic acid
$NH_2PO(OH)_2$	amidophosphoric acid or phosphoramidic acid
$(NH_2)_2PO(OH)$	diamidophosphoric acid or phosphorodiamidic acid

Abbreviated names (sulfamide, phosphamide, sulfamic acid) are often used but are not recommended.

◆The use of adjectives from names of inorganic acids may lead to confusion because an -ic or -ous adjective (as chromic) may refer to a higher- or lower-valent form of the element as well as to the acid (a possibility that does not arise, of course, with adjectives from names of organic acids).

Names of the type phosphoramidic acid are recommended in the report of the Advisory Committee on the Nomenclature of Organic Phosphorus Compounds of the Division of Organic Chemistry of the ACS published in 1952, but are not as acceptable to the inorganic nomenclature committees as a whole as the amido- or cöordination-type names. *Cf.* 3.33.

The retention of sulfamic acid and sulfamide as trivial names is favored by the committees. An acceptable systematic name for NH_2SO_3H would be ammonia-sulfur trioxide, in keeping with its probable structure.

5.35. Nitriles.—The suffix -nitrile has been used in the names of a few inorganic compounds, *e.g.* $(PNCl_2)_3$, trimeric phosphonitrile chloride. According to **2.22** such compounds can be designated as nitrides, *e.g.*, phosphorus nitride dichloride. Accordingly there seems to be no reason for retention of the name nitrile (and nitrilo, *c.f.* **3.33**) in inorganic chemistry.

◆Nitrilo is used in organic chemistry, though not given in the list at the end of the Rules.

6. SALTS AND SALT-LIKE COMPOUNDS

Among salts particularly there persist many old names which are bad and misleading, and the Commission wishes to emphasize that any which do not conform to these Rules should be discarded.

6.1. Simple Salts

Simple salts fall under the broad definition of binary compounds given in Section **2**, and their names are formed from those of the constituent ions (given in Section **3**) in the manner set out in Section **2**.

6.2. Salts Containing Acid Hydrogen ("Acid" Salts[1])

Names are formed by adding the word hydrogen, to denote the replaceable hydrogen present, immediately in front of the name of the anion.

The nonacidic hydrogen present, *e.g.*, in the phosphite ion, is included in the name of the anion and is not explicitly cited (*e.g.*, Na_2PHO_3, sodium phosphite).

Examples:

$NaHCO_3$	sodium hydrogen carbonate
NaH_2PO_4	sodium dihydrogen phosphate
$NaH[PHO_3]$	sodium hydrogen phosphite

◆The use of "fused" hydrogen names (as hydrogencarbonate in the original version) is not acceptable in English; the present practice of running hydrogen as a separate word is preferred and has been followed throughout this version. *Cf.* 3.222, 6.324, 6.333. If necessary for clarity, parentheses can be used, as in naming ligands, *e.g.*, (hydrogen carbonato). The use of hydro (as in hydrocarbonato) is not acceptable because of conflicts with organic usage, where hydro denotes addition of hydrogen to unsaturated compounds.

It seems safer to cite even nonacidic hydrogen present in an anion like PHO_3^{2-} (unless the ion has a specific name), because of current usage. (*Cf.* triethyl phosphite in 7.412, seventh example).

6.3. Double Salts, Triple Salts, etc.

6.31.—In formulas all the cations shall precede the anions; in names the principles embodied in Section 2 shall be applied. In those languages where cation names are placed after anion names the adjectives double, triple, *etc.* (their equivalents in the language concerned) may be added immediately after the anion name. The number so implied concerns the number of *kinds* of cation present and *not* the total number of such ions.

[1]For "basic" salts see 6.4.

6.32.—Cations.

6.321.—Cations shall be arranged in order of increasing valence (except hydrogen, *cf.* **6.2** and **6.324**).

6.322. The cations of each valence group shall be arranged in order of decreasing atomic number, with the polyatomic radical ions (*e.g.*, ammonium) at the end of their appropriate group.

◆Alphabetical order would be simpler here and even for 6.321.

6.323. Hydration of Cations.—Owing to the prevalence of hydrated cations, many of which are in reality complex, it seems unnecessary to disturb the cation order in order to allow for this; but if it is necessary to draw attention specifically to the presence of a particular hydrated cation this may be done by writing, for example, "hexaaquo" or "tetraaquo" before the name of the simple ion. Apart from this exception, however, all complex ions should be placed after simple ones in the appropriate valence group.

◆*Cf.* comment at 7.322.

6.324. Acidic Hydrogen.—When hydrogen is considered to be present as a cation its name shall be cited last among the cations. Actually acidic hydrogen will in most cases be bound to an anion and shall be cited together with this (**6.2**). If the salt contains only one anion, acidic hydrogen shall be cited in the same place whichever view is taken of the function of this hydrogen. Nonacidic hydrogen shall be either not explicitly cited (*cf.* **6.2**) or designated hydrido (*cf.* **5.24** and **7.311**). For salts with more than one anion see **6.333.**

Examples:

$KMgF_3$	potassium magnesium fluoride
$TlNa(NO_3)_2$	thallium(I) sodium nitrate or thallium sodium dinitrate
$KNaCO_3$	potassium sodium carbonate
$NH_4MgPO_4.6H_2O$	ammonium magnesium phosphate hexahydrate
$NaZn(UO_2)_3(C_2H_3O_2)_9.6H_2O$	sodium zinc triuranyl acetate hexahydrate
$Na[Zn(H_2O)_6](UO_2)_3(C_2H_3O_2)_9$	sodium hexaaquozinc triuranyl acetate
$NaNH_4HPO_4.4H_2O$	sodium ammonium hydrogen phosphate tetrahydrate

◆*Cf.* comments at 6.2, 7.312. In the fifth and sixth examples, either triuranyl(VI) or nonaacetate should be specified. *Cf.* 3.32, 6.34.

6.33.—Anions.

6.331.—Anions are to be cited in this group order

1. H^-
2. O_2^- and OH^- (in that order)
3. Simple (*i.e.*, one element only) inorganic anions, other than H^- and O^{2-}
4. Inorganic anions containing two or more elements, other than OH^-
5. Anions of organic acids and organic substances exerting an acid function

◆The committees consider it preferable to cite H^- last in accordance with usage.

6.332.—Within group 3 the ions shall be cited in the order given in **2.16**, the inclusion of O in that list being taken as referring to all oxygen anions apart from O^{2-} (*i.e.*, O_2^{2-}, *etc.*).

Within group 4, anions containing the smallest number of atoms shall be cited first, and in the case of two ions containing the same number of atoms they shall be cited in order of decreasing atomic number of the central atoms. Thus CO_3^{2-} should precede CrO_4^{2-}, and the latter should precede SO_4^{2-}.

Within group 5 the anions shall be cited in alphabetical order.

◆Again alphabetical order would be simpler, within groups 3 and 4 as well as 5. *Cf.* comment at 7.251.

6.333.—Acidic hydrogen should be cited together with the anion to which it is attached. If it is not known to which anion the hydrogen is bound, it should be cited last among the cations.

◆*Cf.* comment at 6.2.

6.34.—The stoichiometric method is the most practicable for indicating the proportions of the constituents. It is not always essential to give the numbers of all the anions, provided the valences of all the cations are either known or indicated.

Examples:

$NaCl.NaF.2Na_2SO_4$ or $Na_6ClF(SO_4)_2$	(hexa)sodium chloride fluoride (bis)sulfate
$Ca_5F(PO_4)_3$	(penta)calcium fluoride (tris)phosphate

The parentheses in these cases mean that numerical prefixes may not be necessary. The multiplicative numerical prefixes bis, tris, *etc.*, should be used in connection with anions, because disulfate, triphosphate, *etc.*, designate isopoly anions.

6.4. Oxide and Hydroxide Salts ("Basic" salts formerly oxy and hydroxy salts)

6.41.—For the purposes of nomenclature, these should be regarded as double salts containing O^{2-} and OH^- anions, and Section **6.3** may be applied in its entirety.

6.42. Use of the Prefixes Oxy and Hydroxy.—In some languages the citation in full of all the separate anion names presents no trouble and is strongly recommended (*e.g.*, copper oxide chloride), to the exclusion of the oxy form wherever possible. In some other languages, however, such names as "oxyde et chlorure double de cuivre" are so far removed from current practice that the present system of using oxy- and hydroxy-, *e.g.*, oxychlorure de cuivre, may be retained in such cases.

Examples:

$Mg(OH)Cl$	magnesium hydroxide chloride
$BiOCl$	bismuth oxide chloride
$LaOF$	lanthanum oxide fluoride
$VOSO_4$	vanadium(IV) oxide sulfate
$CuCl_2.3Cu(OH)_2$ or $Cu_2(OH)_3Cl$	dicopper trihydroxide chloride
$ZrOCl_2.8H_2O$	zirconium oxide (di)chloride octahydrate

6.5. Double Oxides and Hydroxides

The terms "mixed oxides" and "mixed hydroxides" are not recommended. Such substances preferably should be named double, triple, *etc.*, oxides or hydroxides as the case may be.

Many double oxides and hydroxides belong to several distinct groups, each having its own characteristic structure type, which is sometimes named after some well-known mineral of the same group (*e.g.*, perovskite, ilmenite, spinel). Thus, $NaNbO_3$, $CaTiO_3$, $CaCrO_3$, $CuSnO_3$, $YAlO_3$, $LaAlO_3$, and $LaGaO_3$ all have the same structure as perovskite, $CaTiO_3$. Names such as calcium titanate may convey false implications and it is preferable to name such compounds as double oxides and double hydroxides unless there is clear and generally accepted evidence of cations and oxo or hydroxo anions in the structure. This does not mean that names such as titanates or aluminates should always be abandoned, because such substances may exist in solution and in the solid state (*cf.* **3.223**).

◆"Multiple" has been used in English as a class term including double, triple, etc. (oxides or the like).

6.51.—In the double oxides and hydroxides the metals shall be named in the same order as for double salts (**6.32**).

6.52.—When required the structure type may be added in parentheses and in italics after the name, except that when the type name is also the mineral name of the substance itself then the italics should not be used (*cf.* **4.2**).

Examples:

$NaNbO_3$	sodium niobium trioxide (*perovskite* type)
$MgTiO_3$	magnesium titanium trioxide (*ilmenite* type)
$FeTiO_3$	iron(II) titanium trioxide (ilmenite)
$4CaO.AL_2O_3.nH_2O$ or $Ca_2Al(OH)_7.nH_2O$	dicalcium aluminum hydroxide hydrate
but $Ca_3[Al(OH)_6]_2$	(tri)calcium (bis)-[hexahydroxoaluminate]
$LiAl(OH)_4.2MnO_2$ or $LiAlMn^{IV}_2O_4(OH)_4$	lithium aluminum dimanganese(IV) tetraoxide tetrahydroxide

7. COÖRDINATION COMPOUNDS

7.1. Definitions

In its oldest sense the term *coördination compound* is taken as referring to molecules or ions in which there is an atom (A) to which are attached other atoms (B) or groups (C) to a number in excess of that corresponding to the oxidation number of the atom A. However, the system of nomenclature originally evolved for the compounds within this narrow definition has proved useful for a much wider class of compounds, and for the purposes of nomenclature the restriction "in excess . . . oxidation number" is to be omitted. Any compound formed by addition of one or several ions and/or molecules to one or more ions or/and molecules may be named according to the same system as strict coördination compounds.

The effect of this is to bring many simple and well-known compounds under the same nomenclature rules as accepted coöordination compounds; the result is to reduce the diversity of names and avoid many controversial issues, because it should be understood that there is no intention of implying that any structural analogy necessarily exists between different compounds merely on account of a common system of nomenclature. The system extends also to many addition compounds.

In the rules which follow certain terms are used in the senses here indicated: the atom referred to above as (A) is known as the *central* or *nuclear* atom, and all other atoms which are directly attached to A are known as *coördinating atoms*. Atoms (B) and groups (C) are called *ligands*. A group containing more than one *potential* coördinating atom is termed a *multidentate* ligand, the number of potential coöordinating atoms being indicated by the terms *unidentate, bidentate, etc.* A *chelate* ligand is a ligand *attached* to *one* central atom through *two or more* coördinating atoms, while a *bridging group* is attached to *more than one* atom. The whole assembly of one or more central atoms with their attached ligands is referred to as a *complex*, which may be an uncharged molecule or an ion of either polarity. A *polynuclear complex* is a complex which contains *more than one* nuclear atom, their number being designated by the terms *mononuclear, dinuclear, etc.*

◆Some dissatisfaction with the definition of coördination compounds was expressed, though the broad definition (last sentence of first paragraph) was generally approved.

Central atom or *center of coördination* is to be preferred to *nuclear* atom because of other senses of nucleus, especially of an atom. Possible replacements for polynuclear, etc., are polycentric, *etc.*, or bridged complex since bridging group is in common use.

In the United States the Greek-Latin hybrid terms polydentate and monodentate seem to be used more than the all-Latin multidentate and unidentate.

7.2. Formulas and Names for Complex Compounds in General

7.21. Central Atoms.—In *formulas* the symbol for the central atom(s) should be placed *first* (except in formulas which are primarily structural), the anionic and neutral, *etc.*, ligands following as prescribed in **7.25**, and the formula for the whole complex entity (ion or molecule) should be placed in brackets [ ].

In *names* the central atom(s) should be placed *after* the ligands.

◆It is considered preferable to place the whole complex in brackets, especially when more than one central atom is present, but not essential with only one central atom or with complex ions or nonionic complexes, because brackets may be needed sometimes for indicating concentrations.

7.22. Indication of Valence and Proportion of Constituents.—The oxidation number of the central atom is indicated by means of the Stock notation (**2.252**). Alternatively the proportion of constituents may be given by means of stoichiometric prefixes (**2.251**).

7.23.—Formulas and names may be supplemented with the prefixes *cis, trans, etc.* (**2.19**).

7.24. Terminations.—Complex anions shall be given the termination -ate (*cf.* **2.23**, **2.24** and **3.223**). Complex cations and neutral molecules are given no distinguishing termination. For further details concerning the names of ligands see **7.3.**

7.25. Order of Citation of Ligands in Complexes.—

first: anionic ligands
next: neutral and cationic ligands

7.251.—The anionic ligands shall be cited in the order

1. H^-
2. O^{2-}, OH^- (in that sequence)
3. Other simple anions (*i.e.*, one element only)
4. Polyatomic anions
5. Organic anions in alphabetical order

The sequence within categories 3 and 4 should be that given in **6.332.**

◆H^- is preferably named last, not first (*cf.* comment at 6.331). Alphabetical order is strongly recommended for simplicity at least within 3 and 4, where only rare uses are involved. The intention seems to be to include under 3 monatomic ions (*i.e.*, one *atom*—rather than one *element*—only), in other words to exclude N_3, I_3, etc. Under 4 the insertion of "inorganic" between "Polyatomic" and "anions" is recommended.

7.252.—Neutral and cationic ligands shall be cited in the order given

first: water, ammonia (in that sequence)
then: other inorganic ligands in the sequence in which their coördinating elements appear in the list given in **2.16**
last: organic ligands in alphabetical order.

◆For the inorganic ligands alphabetical order again is recommended. The use of parentheses wherever there is any possibility of ambiguity should be stressed, as illustrated in examples under 7.321: potassium trichloro(ethylene)platinate(II), where parentheses are given in the Rules, and tetra(pyridine)platinum(II) tetrachloroplatinate(II), where they have been added in this version. Parentheses might also be helpful with "thiocyanato" preceded by a numerical prefix (see last example in 7.311) and are definitely required with two-word names for ligands recommended instead of the fused names of the original version (6.2), as in the seventh example in 7.412: di-μ-carbonyl-bis{carbonyl(triethyl phosphite)cobalt}. Since brackets denote complexes, braces can be used in formulas or names where needed in order to avoid the use of two sets of parentheses (braces were so used in some but not all such cases in the original version).

7.3. Names for Ligands

7.31.—Anionic Ligands.

7.311.—The names for anionic ligands, whether inorganic or organic, end in -o (see, however, **7.324**). In general, if the anion name ends in -ide, -ite, or -ate, the final -e is replaced by -o, giving -ido, -ito, and -ato, respectively.

Examples:

$Li[AlH_4]$	lithium tetrahydridoaluminate
$Na[BH_4]$	sodium tetrahydridoborate
$K_2[OsNCl_5]$	potassium nitridopentachloroösmate(VI)
$[Co(NH_2)_2(NH_3)_4]OC_2H_5$	diamidotetraamminecobalt(III) ethanolate
$[CoN_3(NH_3)_5]SO_4$	azidopentaamminecobalt(III) sulfate
$Na_3[Ag(S_2O_3)_2]$	sodium bis(thiosulfato)argentate(I)
$[Ru(HSO_3)_2(NH_3)_4]$	bis(hydrogen sulfito)tetraammineruthenium
(II) $NH_4[Cr(SCN)_4(NH_3)_2]$	ammonium tetrathiocyanatodiamminechromate (III)

◆For "ethanolate" in the fourth example "ethoxide" may be preferred.

7.312.—These anions do not follow exactly the above rule; modified forms have become established:

F^-	fluoride	fluoro (*not* fluo)	O_2^{2-}	peroxide	peroxo
Cl^-	chloride	chloro	HS^-	hydrogen sulfide	thiolo
Br^-	bromide	bromo	S^{2-}	sulfide	thio[1] (sulfido)
I^-	iodide	iodo	(but:S_2^{2-}	disulfide	disulfido)
O^{2-}	oxide	oxo	CN^-	cyanide	cyano
OH^-	hydroxide	hydroxo			

[1]The name thio has long been used to denote the ligand S^{2-} when it can be regarded as replacing O^{2-} in an oxo acid or its anion. The general use of this name will prevent confusion between the two interpretations of disulfido as S_2^{2-} or two S^{2-} ligands.

By analogy with hydroxo, CH_3O^-, *etc.*, are called methoxo, *etc.* For CH_3S^-, *etc.*, the systematic names methanethiolato, *etc.*, are used.

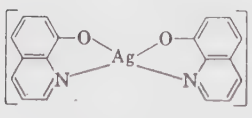
Examples:

$K[AgF_4]$	potassium tetrafluoroargentate(III)
$K_2[NiF_6]$	potassium hexafluoroniccolate(IV)
$Ba[BrF_4]_2$	barium tetrafluorobromate(III)
$Na[AlCl_4]$	sodium tetrachloroaluminate
$Cs[ICl_4]$	cesium tetrachloroiodate(III)
$K[Au(OH)_4]$	potassium tetrahydroxoaurate(III)
$K[CrOF_4]$	potassium oxotetrafluorochromate(V)
$K_2[Cr(O)_2O_2(CN)_2(NH_3)]$	potassium dioxoperoxodicyanoamminechromate(VI)
$Na[BH(OCH_3)_3]$	sodium hydridotrimethoxoborate
$K_2[Fe_2S_2(NO)_4]$	dipotassium dithiotetranitrosyldiferrate

◆It is strongly recommended on the basis of past and present usage, analogy with chloro, *etc.*, and euphony that hydro be added to the list of modified forms of names for anionic ligands and that hydrido be abandoned (*cf.* also examples in 7.311).

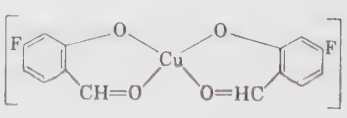
While the Subcommittee on Coördination Compounds recognizes the usefulness of the invariable -o ending for anionic ligands, some members of the general committees do not see a sharp enough distinction between such ligands and the same groups in organic compounds to justify a departure from organic usage by using hydroxo, methoxo, *etc.*, instead of hydroxy, methoxy, *etc.* These members therefore favor adding hydroxy, methoxy, *etc.*, to the hydrocarbon radicals excepted from the rule of -o endings for anions (7.324). For the use of peroxo, see comment at 5.22.

The -o of a negative ligand should not be elided before another vowel (chloroösmate, chloroiodo). This agrees with organic practice. *Cf.* comment at 7.322.



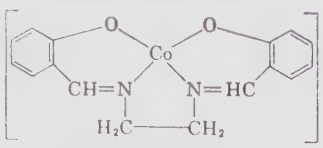
It should be pointed out here as well as in the list of names for ions and radicals at the end of the Rules that the approved organic name for unsubstituted HS is mercapto (not thiol, as also given in the list) and for the alkyl- and aryl-substituted radicals methylthio, *etc.*

7.313.—Ligands derived from organic compounds not normally called acids, but which function as such in complex formation by loss of a proton, should be treated as anionic and given the ending -ato. If, however, no proton is lost, the ligand must be treated as neutral—see **7.32.**



Examples:

$[Ni(C_4H_7N_2O_2)_2]$ bis(dimethylglyoximato)nickel(II)



$[Cu(C_5H_7O_2)_2]$ bis(acetylacetonato)copper(II)

bis(8-quinolinolato)silver(II)

bis(4-fluorosalicylaldehydato)copper(II)

N,N'-ethylenebis(salicylideneiminato)cobalt(II)

◆Although according to 3.33 the name for the ligand in the second example should be derived from the systematic name 2,4-pentanedione instead of from acetylacetone, acetylacetonato perhaps conveys better the idea that it is the enol form that is involved. However, the coördination subcommittee questions the use of the termination -ato rather than plain -o especially in cases where the -ate terms (as dimethylglyoximate) are not accepted organic practice. Such -ato terms are especially misleading in the last two examples, where the -ato belongs with the hydroxyl part of the name, not the aldehyde or imine part to which it is attached.

7.32.—Neutral and Cationic Ligands.

7.321.—The name of the coördinated molecule or cation is to be used without change, except in the special cases provided for in **7.322.**

Examples:

$[CoCl_2(C_4H_8N_2O_2)_2]$	dichlorobis(dimethylglyoxime)cobalt(II) (*cf.* nickel derivative given in **7.313**)
cis-$[PtCl_2(Et_3P)_2]$	*cis*-dichlorobis(triethylphosphine)platinum(II)
$[CuCl_2(CH_3NH_2)_2]$	dichlorobis(methylamine)copper(II)
[Pt py_4] [$PtCl_4$]	tetra(pyridine)platinum(II) tetrachloroplatinate(II)
$[Fe(dipy)_3]Cl_2$	tris(dipyridyl)iron(II) chloride
$[Co\ en_3]_2(SO_4)_3$	tris(ethylenediamine)cobalt(III) sulfate
$[Zn\{NH_2CH_2CH(NH_2)CH_2NH_2\}_2]I_2$	bis(1,2,3-triaminopropane)zinc iodide
$K[PtCl_3(C_2H_4)]$	potassium trichloro(ethylene)platinate(II) or potassium trichloromonoethyleneplatinate(II)
$[PtCl_2\{H_2NCH_2CH(NH_2)CH_2NH_3\}]Cl$	dichloro(2,3 - diaminopropylammonium)platinum(II) chloride
$[Cr(C_6H_5NC)_6]$	hexakis(phenyl isocyanide)chromium

◆In the fifth example, bipyridine is preferred to dipyridyl in organic practice, and in the seventh example 1,2,3-propanetriamine to 1,2,3-triaminopropane.

7.322.—Water and ammonia as neutral ligands in coördination complexes are called "aquo" and "ammine," respectively.

In the tentative rules it was proposed to change the old-established "aquo" to "aqua," thus keeping the -o termination consistently for anionic ligands alone. However, as the old form is so widely used, many regarded the change as too pedantic, and the Commission has decided to retain "aquo" as an exception.

Examples:

$[Cr(H_2O)_6Cl_3$	hexaaquochromium(III) chloride or hexaaquochromium trichloride
$[Al(OH)(H_2O)_5]^{++}$	the hydroxopentaaquoaluminum ion
$[Co(NH_3)_6]ClSO_4$	hexaamminecobalt(III) chloride sulfate
$[CoCl(NH_3)_5]Cl_2$	chloropentaamminecobalt(III) chloride
$[CoCl_3(NH_3)_2\{(CH_3)_2NH\}]$	trichlorodiammine(dimethylamine)cobalt(III)

◆Hexaquo, pentaquo, *etc.*, are used in the examples in the original version, but have been changed in this version to hexaaquo, *etc.*, for conformity with the latest approved organic practice. (*Cf.* hexaammonium, given with two a's separated by a hyphen in 7.6, second example, in the original version.)

7.323.—The groups NO, NS, CO, and CS, when linked directly to a metal atom, are to be called nitrosyl, thionitrosyl, carbonyl, and thiocarbonyl, respectively. In computing the oxidation number these radicals are treated as neutral.

Examples:

$Na_2[Fe(CN)_5NO]$	disodium pentacyanonitrosylferrate
$K_3[Fe(CN)_5CO]$	tripotassium pentacyanocarbonylferrate
$K[Co(CN)(CO)_2(NO)]$	potassium cyanodicarbonylnitrosylcobaltate(0)
$HCo(CO)_4$	hydrogen tetracarbonylcobaltate($-I$)
$[Ni(CO)_2(Ph_3P)_2]$	dicarbonylbis(triphenylphosphine)nickel(0)
[Fe en_3] [$Fe(CO)_4$]	tris(ethylenediamine)iron(II) tetracarbonylferrate ($-II$)
$Mn_2(CO)_{10}$ or $[CO_5)Mn–Mn(CO)_5]$	decacarbonyldimanganese(0) or bis(pentacarbonylmanganese)

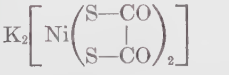
◆The necessity of arbitrarily considering these groups as always neutral can be avoided by not using the oxidation number but instead the stoichiometric proportions (as in some of these examples) or the Ewens-Bassett system (*cf.* comment at 2.252). Thus the anion in the last example in 7.312 (where NO is known to be positive) would by this system be named dithiotetranitrosyldiferrate (2–).

7.324.—Anions derived from hydrocarbons are given radical names without -o, but are counted as negative when computing the oxidation number.

The consistent introduction of the ending -o would in this case lead to unfamiliar names, *e.g.*, phenylato or phenido for $C_6H_5^-$. On the other hand, if the radicals were counted as neutral ligands, the central atom would have to be given an unusual oxidation number, *e.g.*, $-I$ for boron in $K[B(C_6H_5)_4]$, instead of III.

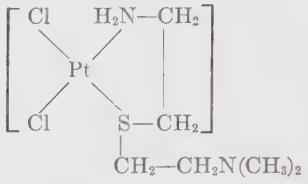
Examples:

$K[B(C_6H_5)_4]$	potassium tetraphenylborate
$K[SbCl_5C_6H_5]$	potassium pentachloro(phenyl)antimonate(V)
$K_2[Cu(C_2H)_3]$	potassium triethynylcuprate(I)
$K_4[Ni(C_2C_6H_5)_4]$	potassium tetrakis(phenylethynyl)niccolate(0)
$[Fe(CO)_4(C_2C_6H_5)_2]$	tetracarbonylbis(phenylethynyl)iron(II)
$Fe(C_5H_5)_2$	bis(cyclopentadienyl)iron(II)
$[Fe(C_5H_5)_2]Cl$	bis(cyclopentadienyl)iron(III) chloride
$[Ni(NO)(C_5H_5)]$	nitrosylcyclopentadienylnickel



◆The use of radical names such as cyclopentadienyl in the examples does not seem consistent with the use of Stock notations; for the sixth example ("ferrocene"), iron(II) cyclopentadienide is preferred by some. This matter is presumably part of the whole organometallic problem to be dealt with by the new IUPAC joint organic-inorganic subcommittee.

For niccolate, see comment at 1.12.



7.33.—Alternative Modes of Linkage of Some Ligands.—Where ligands are capable of attachment by different atoms this may be denoted by adding the symbol for the atom by which attachment occurs at the end of the name of the ligand. Thus the dithioöxalato group may be attached through S or O, and these are distinguished as dithioöxalato-*S,S′* and dithioöxalato-*O,O′*, respectively.

In some cases different names are already in use for alternative modes of attachment, as, for example, thiocyanato (−SCN) and isothiocyanato (−NCS), nitro ($-NO_2$), and nitrito (−ONO). In these cases existing custom may conveniently be retained.

Examples:

potassium bis(dithioöxalato-*S,S′*)niccolate(II)

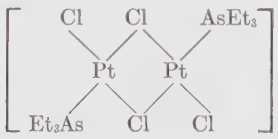
dichloro(2-*N,N*-dimethylaminoethyl 2-aminoethyl sulfide-*N′,S*)platinum(II)

$K_2[Pt(NO_2)_4]$	potassium tetranitroplatinate(II)
$Na_3[Co(NO_2)_6]$	sodium hexanitrocobaltate(III)
$[Co(NO_2)_3(NH_3)_3]$	trinitrotriamminecobalt(III)
$[Co(ONO)(NH_3)_5]SO_4$	nitritopentaamminecobalt(III) sulfate
$[Co[NCS)(NH_3)_5]Cl_2$	isothiocyanatopentaamminecobalt(III) chloride

◆Thioöxalato in the original version has been changed to dithioöxalato.

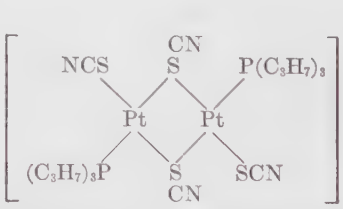
7.4. Di- and Polynuclear Compounds

7.41.—Bridging Groups.



7.411.—A bridging group shall be indicated by adding the Greek letter μ immediately before its name and separating this from the rest of the complex by a hyphen. Two or more bridging groups of the same kind are indicated by di-μ-, *etc.*

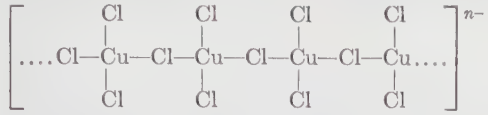
7.412.—If the number of central atoms bound by one bridging group exceeds two, the number shall be indicated by adding a subscript numeral to the μ.



This system of notation allows simply of distinction between, for example, μ-disulfido (one S_2 bridge) and di-μ-sulfido (two S bridges). It is also capable of extension to much more complex and unsymmetrical structures by use of the conventional prefixes *cis, trans, asym,* and *sym* where necessary.

Examples:

$[(NH_3)_5Cr–OH–Cr(NH_3)_5]Cl_5$
μ-hydroxo-bis{pentaamminechromium(III)}chloride



di-μ-chloro-dichlorobis(triethylarsine)diplatinum (II) (three possible isomers: *asym, sym-cis,* and *sym-trans;* the last is shown)

di-μ-thiocyanato-dithiocyanatobis(tripropylphosphine)diplatinum(II)

$[(CO)_3Fe(CO)_3Fe(CO)_3]$	tri-μ-carbonyl-bis(tricarbonyliron)
$[(CO)_3Fe(SEt)_2Fe(CO)_3]$	di-μ-ethanethiolato-bis(tricarbonyliron)
$[(C_5H_5)(CO)Fe(CO)_2Fe(CO)(C_5H_5)]$	di-μ-carbonyl-bis(carbonylcyclopentadienyliron)
$[(CO)\{P(OEt)_3\}Co(CO)_2Co(CO)\{P(OEt)_3\}]$	di-μ-carbonyl-bis{carbonyl(triethyl phosphite)-cobalt}
$[Au(CN)(C_3H_7)_2]_4$	cyclo-tetra-μ-cyano-tetrakis(dipropylgold)
$[CuI(Et_3As)]_4$	tetra-μ_3-iodo-tetrakis{triethylarsinecopper(I)}
$[Be_4O(CH_3COO)_6]$	μ_4-oxo-hexa-μ-acetato-tetraberyllium

7.42. Extended Structures.—Where bridging causes an indefinite extension of the structure it is best to name compounds primarily on the basis of their over-all composition; thus the compound having the composition represented by the formula $CsCuCl_3$ has an anion with the structure:

This may be expressed in the formula $(Cs^+)_n^-$ $[(CuCl_3)_n]^{n-}$ which leads to the simple name cesium catena-μ-chloro-dichlorocuprate(II). If the structure were in doubt, however, the substance would be called cesium copper(II) chloride (as a double salt).

◆*Cf.* comment on *catena* at 1.4.

7.5. Isopoly Anions

The structure of many complicated isopoly anions has now been cleared up by X-ray work and it turns out that the indication of the several μ-oxo and oxo atoms in the name does not convey any clear picture of the structure and is therefore of little value.

For the time being it is sufficient to indicate the number of atoms by Greek prefixes, at least until isomers are found. When all atoms have their "normal" oxidation states (*e.g.*, W^{VI}), it is not necessary to give the numbers of the oxygen atoms, if all the others are indicated.

Examples:

$K_2S_2O_7$	dipotassium disulfate
$K_2S_3O_{10}$	dipotassium trisulfate
$Na_5P_3O_{10}$	pentasodium triphosphate
$K_2Cr_4O_{13}$	dipotassium tetrachromate
$Na_2B_4O_7$	disodium tetraborate
NaB_5O_8	sodium pentaborate
$Ca_3Mo_7O_{24}$	tricalcium heptamolybdate
$Na_7HNb_6O_{19}.15H_2O$	heptasodium monohydrogen hexaniobate-15-water
$K_2Mg_2V_{10}O_{28}.16H_2O$	dipotassium dimagnesium decavanadate-16-water

7.6. Heteropoly Anions

The central atom or atoms should be cited last in the name and first in the formula of the anion (*cf.* **7.21**), *e.g.*, wolframophosphate, *not* phosphowolframate.

If the oxidation number has to be given, it may be necessary to place it immediately after the atom referred to and not after the ending -ate, in order to avoid ambiguity.

The method formerly recommended for naming iso- and heteropoly anions by giving the number of atoms in parentheses is not practicable in more complicated cases.

Examples:

$(NH_4)_3PW_{12}O_{40}$	triammonium dodecawolframophosphate
$(NH_4)_6TeMo_6O_{24}.7H_2O$	hexaammonium hexamolybdotellurate heptahydrate
$Li_3HSiW_{12}O_{40}.24H_2O$	trilithium (mono)hydrogen dodecawolframosilicate-24-water
$K_6Mn^{IV}Mo_9O_{32}$	hexapotassium enneamolybdomanganate(IV)
$Na_6P^{V}_2Mo_{18}O_{62}$	hexasodium 18-molybdodiphosphate(V)
$Na_4P^{III}_2Mo_{12}O_{41}$	tetrasodium dodecamolybdodiphosphate(III)
$K_7Co^{II}Co^{III}W_{12}O_{42}.16H_2O$	heptapotassiumdodecawolframocobalt(II)-cobalt(III)ate-16-water
$K_3PV_2Mo_{10}O_{39}$	tripotassium decamolybdodivanadophosphate

◆The coördination subcommittee would prefer not to have sections 7.5 and 7.6 included under 7 and recommends that they should be studied by a special subcommittee. Some cyclic isomers are already known, and isopoly cations also are being investigated.

Cf. comment at 1.12 for stand on wolframate and wolframo, and 2.251 for nona instead of ennea (fourth example).

Isopoly and heteropoly are not separate words in the original version.

7.7. Addition Compounds

The ending -ate is now the accepted ending for *anions* and should generally not be used for addition compounds. Alcoholates are the *salts* of alcohols and this name should not be used to indicate alcohol of crystallization. Analogously addition compounds containing ether, ammonia, *etc.*, should *not* be termed etherates, ammoniates, *etc.*

However, one exception has to be recognized. According to the commonly accepted meaning of the ending -ate, "hydrate" would be, and was formerly regarded as, the name for a *salt* of water, *i.e.*, what is now known as a hydroxide; the name hydrate has now a very firm position as the name of a compound containing water of crystallization and is allowed also in these Rules to designate water bound in an unspecified way; it is considered to be preferable even in this case to avoid the ending -ate by using the name "water" (or its equivalent in other languages) when possible.

The names of addition compounds may be formed by connecting the names of individual compounds by hyphens (short dashes) and indicating the number of molecules by Arabic numerals. When the added molecules are organic, however, it is recommended to use multiplicative numeral prefixes (bis, tris, tetrakis, *etc.*) instead of Arabic figures to avoid confusion with the organic-chemical use of Arabic figures to indicate position of substituents.

Examples:

$CaCl_2.6H_2O$	calcium chloride–6-water (or calcium chloride hexahydrate)
$3CdSO_4.8H_2O$	3-cadmium sulfate–8-water
$Na_2CO_3.10H_2O$	sodium carbonate–10-water (or sodium carbonate decahydrate)
$AlCl_3.4C_2H_5OH$	aluminum chloride–4-ethanol or –tetrakisethanol
$BF_3.(C_2H_5)_2O$	boron trifluoride–diethyl ether
$BF_3.2CH_3OH$	boron trifluoride–bismethanol
$BF_3.H_3PO_4$	boron trifluoride–phosphoric acid
$BiCl_3.3PCl_5$	bismuth trichloride–3-(phosphorus pentachloride)
$TeCl_4.2PCl_5$	tellurium tetrachloride–2-(phosphorus pentachloride)
$(CH_3)_4NAsCl_4.2AsCl_3$	tetramethylammonium tetrachloroarsenate(III)–2-(arsenic trichloride)
$CaCl_2.8NH_3$	calcium chloride–8-ammonia
$8H_2S.46H_2O$	8-(hydrogen sulfide)–46-water
$8Kr.46H_2O$	8-krypton–46-water
$6Br_2.46H_2O$	6-dibromine–46-water
$8CHCl_3.16H_2S.136H_2O$	8-chloroform–16-(hydrogen sulfide)–136-water

These names are not very different from a pure verbal description which may in fact be used, *e.g.*, calcium chloride with 6 water, compound of aluminum chloride with 4 ethanol, *etc.*

If it needs to be shown that added molecules form part of a complex, the names are given according to **7.2** and **7.3.**

Examples:

$FeSO_4.7H_2O$ or $[Fe(H_2O)_6]SO_4.H_2O$	iron(II) sulfate heptahydrate or hexaaquoiron(II) sulfate monohydrate
$PtCl_2.2PCl_3$ or $[PtCl_2(PCl_3)_2]$	platinum(II) chloride–2-(phosphorus trichloride) or dichlorobis(phosphorus trichloride)-platinum(II)
$AlCl_3.NOCl$ or $NO[AlCl_4]$	aluminum chloride–nitrosyl chloride or nitrosyl tetrachloroaluminate
$BF_3.Et_3N$ or $[BF_3(Et_3N)]$	boron trifluoride–triethylamine or trifluoro(triethylamine)boron

◆Only some so-called "addition compounds" are known to be coordination compounds, and the formulas and names can show such structures. Those that are lattice compounds and those of unknown structure do not really belong in 7.

The committees like hydrate and ammoniate and see no particular advantage in dropping them (*cf.* the use of hydrate terms in examples in 6.324; 6-hydrate, *etc.*, as well as hexahydrate, *etc.*, are considered acceptable).

No reason can be seen for deviating here from usual organic practice by using multiplicative prefixes with simple names: tetraethanol is just as clear as tetrakisethanol, and dimethanol as bismethanol. Parentheses can always be used if there is danger of any ambiguity.

The use of short dashes ("en" dashes) instead of hyphens between the names (as in the examples here, but not in the original version) makes for greater ease in reading.

It is considered preferable by some to place the electron donor first in both the formulas and name: $(C_2H_5)_2O.BF_3$, diethyl ether–boron trifluoride (note that organic usage favors ethyl ether over diethyl ether).

8. POLYMORPHISM

Minerals occurring in nature with similar compositions have different names according to their crystal structures; thus, zinc blende, wurtzite; quartz, tridymite, and cristobalite. Chemists and metallographers have designated polymorphic modifications with Greek letters or with Roman numerals (α-iron, ice-I, *etc.*). The method is similar to the use of trivial names, and is likely to continue to be of use in the future in cases where the existence of polymorphism is established, but not the structures underlying it. Regrettably there has been no consistent system, and some investigators have designated as α the form stable at ordinary temperatures, while others have used α for the form stable immediately below the melting point, and some have even changed an already established usage and renamed α-quartz β-quartz, thereby causing confusion. If the α–β nomenclature is used for two substances A and B, difficulties are encountered when the binary system A–B is studied.

LIST OF NAMES FOR IONS AND RADICALS

In inorganic chemistry substitutive names seldom are used, but the organic-chemical names are shown to draw attention to certain differences between organic and inorganic nomenclature.

Atom or group	Name as neutral molecule	as cation or cationic radical[1]	as anion	as ligand	as prefix for substituent in organic compounds
H	monohydrogen	hydrogen	hydride	hydrido	
F	monofluorine		fluoride	fluoro	fluoro
Cl	monochlorine	chlorine	chloride	chloro	chloro
Br	monobromine	bromine	bromide	bromo	bromo
I	monoiodine	iodine	iodide	iodo	iodo
I_3			triiodide		
ClO		chlorosyl	hypochlorite	hypochlorito	
ClO_2	chlorine dioxide	chloryl	chlorite	chlorito	
ClO_3		perchloryl	chlorate	chlorato	
ClO_4			perchlorate		
IO		iodosyl	hypoiodite		iodoso
IO_2		iodyl			iodyl or iodoxy
O	monoöxygen		oxide	oxo	oxo or keto
O_2	dioxygen		O_2^{2-}: peroxide	peroxo	peroxy
			O_2^-: hyperoxide		
HO	hydroxyl		hydroxide	hydroxo	hydroxy
HO_2	(perhydroxyl)		hydrogen peroxide	hydrogen peroxo	hydroperoxy
S	monosulfur		sulfide	thio (sulfido)	thio
HS	(sulfhydryl)		hydrogen sulfide	thiolo	thiol or mercapto
S_2	disulfur		disulfide	disulfido	
SO	sulfur monoxide	sulfinyl (thionyl)			sulfinyl
SO_2	sulfur dioxide	sulfonyl (sulfuryl)	sulfoxylate		sulfonyl
SO_3	sulfur trioxide		sulfite	sulfito	
HSO_3			hydrogen sulfite	hydrogen sulfito	
S_2O_3			thiosulfate	thiosulfato	
SO_4			sulfate	sulfato	
Se	selenium		selenide	seleno	seleno
SeO		seleninyl			seleninyl
SeO_2		selenonyl			selenonyl
SeO_3	selenium trioxide		selenite	selenito	
SeO_4			selenate	selenato	
Te	tellurium		telluride	telluro	telluro
CrO_2		chromyl			
UO_2		uranyl			
NpO_2		neptunyl			
PuO_2		plutonyl			
AmO_2		americyl			
N	mononitrogen		nitride	nitrido	
N_3			azide	azido	
NH			imide	imido	imino
NH_2			amide	amido	amino
NHOH			hydroxylamide	hydroxylamido	hydroxylamino
N_2H_3			hydrazide	hydrazido	hydrazino
NO	nitrogen oxide	nitrosyl		nitrosyl	nitroso
NO_2	nitrogen dioxide	nitryl		nitro	nitro
ONO			nitrite	nitrito	
NS		thionitrosyl			
$(NS)_n$		thiazyl (*e.g.*, trithiazyl)			
NO_3			nitrate	nitrato	
N_2O_3			hyponitrite	hyponitrito	
P	phosphorus		phosphide	phosphido	
PO		phosphoryl			phosphoroso
PS		thiophosphoryl			
PH_2O_3			hypophosphite	hypophosphito	
PHO_3			phosphite	phosphito	
PO_4			phosphate	phosphato	
AsO_4			arsenate	arsenato	
VO		vanadyl			
CO	carbon monoxide	carbonyl		carbonyl	carbonyl
CS		thiocarbonyl			
CH_3O	methoxyl		methanolate	methoxo	methoxy
C_2H_5O	ethoxyl		ethanolate	ethoxo	ethoxy
CH_3S			methanethiolate	methanethiolato	methylthio
C_2H_5S			ethanethiolate	ethanethiolato	ethylthio
CN		cyanogen	cyanide	cyano	cyano
OCN			cyanate	cyanato	cyanato
SCN			thiocyanate	thiocyanato and isothiocyanato	thiocyanato and isothiocyanato
SeCN			selenocyanate	selenocyanato	selenocyanato
TeCN			tellurocyanate	tellurocyanato	
CO_3			carbonate	carbonato	
HCO_3			hydrogen carbonate	hydrogen carbonato	
CH_3CO_2			acetate	acetato	acetoxy
CH_3CO	acetyl	acetyl			acetyl
C_2O_4			oxalate	oxalato	

[1]If necessary, oxidation state is to be given by Stock notation.

◆Although some additions might be made to this list, especially in the last column, and a few changes suggested, no attempt has been made to do so at this time. *Cf.* comments at such rules as 3.31, 3.32, 5.35, 6.2, and 7.312.

A rational system should be based upon crystal structure, and the designations α, β, γ, *etc.*, should be regarded as provisional, or as trivial names. The designations should be as short and understandable as possible, and convey a maximum of information to the reader. The rules suggested here have been framed as a basis for future work, and it is hoped that experience in their use may enable more specific rules to be formulated at a later date.

8.1.—For chemical purposes (*i.e.*, when particular mineral occurrences are not under consideration) polymorphs should be indicated by adding the crystal system after the name or formula. For example, zinc sulfide(cub.) or ZnS(cub.) corresponds to zinc blende or sphalerite, and ZnS(hex.) to wurtzite. The Commission considers that these abbreviations might with advantage be standardized internationally:

cub.	=	cubic	hex.	=	hexagonal
c.	=	body-centered	trig.	=	trigonal
f.	=	face-centered	mon.	=	monoclinic
tetr.	=	tetragonal	tric.	=	triclinic
o-rh.	=	orthorhombic			

Slightly distorted lattices may be indicated by use of the *circa* sign, $\sim$. Thus, for example, a slightly distorted face-centered cubic lattice would be expressed as $\sim$f.cub.

8.2.—Crystallographers may find it valuable to add the space-group; it is doubtful whether this system would commend itself to chemists where **8.1** is sufficient.

8.3.—Simple well-known structures may also be designated by giving the type-compound in italics in parentheses; but this system often breaks down because many structures are not referable to a type in this way. Thus, AuCd above 70° may be written as AuCd(cub.) or as AuCd(*CsCl-type*); but at low temperature only as AuCd(o-rh.), as its structure cannot be referred to a type.

◆*Cf.* 6.5 and 6.52.

ABBREVIATIONS USED IN TABLE OF PHYSICAL CONSTANTS OF INORGANIC COMPOUNDS

a	acid
abs	absolute
ac. a	acetic acid
acet	acetone
act	active
al	alcohol
alk	alkali
amm	ammonium
amor	amorphous
anh	anhydrous
appr	approximately
aq	aqua, water
aq. reg	aqua regia
